

CrypTool 2.0

Plugin Developer Manual

– How to build your own plugins for CrypTool 2.0 –

S. Przybylski, A. Wacker, M. Wander, F. Enkler and P. Vacek
{przybylski|wacker|wander|enkler|vacek}@cryptool.org

Version: 0.5
May 31, 2010

CrypTool 2 is the modern successor of the well-known e-learning platform for cryptography and cryptanalysis [CrypTool 1](#), which is used worldwide for educational purposes at schools and universities as well as in companies and agencies.

Since the first launch of CrypTool 1 in 1999 the art of software development has changed dramatically. The CrypTool 2 team began working in 2008 to develop a completely new e-learning application, embracing the newest trends in both didactics and software architecture to delight the end-user with an entirely new experience.

To reach these goals, CrypTool 2 is built using the following:

- .NET (a modern software framework from Microsoft with solutions to common programming problems)
- C# (a modern object-oriented programming language, comparable to Java)
- WPF (a modern purely vector-based graphical subsystem for rendering user interfaces in Windows-based applications)
- Visual Studio 2008 (a development environment)
- Subversion (a source code and documentation version management system)

This document is intended for plugin developers who want to contribute new visual or mathematical functionality to CrypTool 2. As of January 2010, the program consists of over 7000 lines of C# code in the core application and over 250,000 lines of C# code in about 100 plugins.

For further information, please visit the CrypTool 2 website at <http://www.cryptool2.vs.uni-due.de>.

1 Developer Guidelines

CrypTool 2.0 is built upon state-of-the-art technologies such as .NET 3.5 and the Windows Presentation Foundation. Before you can start writing code and adding to the development of the project, a few things need to be considered. To make this process easier, please read through this document and follow the instructions closely. This document exists to help get you started by showing you how CrypTool 2 plugins are built in order to successfully interact with the application core. We have tried to be very thorough, but if you encounter a problem or error that is not described here, please let us know. Not only do we want to help get you up and running, but we also want to add the appropriate information to this guide for the benefit of other future developers.

In this first chapter we will describe all steps necessary in order to compile CrypTool 2 on your own computer. This is always the first thing you need to do before you can begin developing your own plugins and extensions. The basic steps are:

- Getting all prerequisites and installing them
- Accessing and downloading the source code with SVN
- Compiling the latest version of the source code

1.1 Prerequisites

Since CrypTool 2 is based on Microsoft .NET 3.5, you will need a Microsoft Windows environment. (Currently no plans exist for porting this project to Mono or other platforms.) We have successfully tested with **Windows XP**, **Windows Vista** and **Windows 7**.

Since you are reading the developer guidelines, you probably want to develop something. Hence, you will need a development environment. In order to compile our sources you need **Microsoft Visual Studio 2008 Professional**. Make sure to always install the latest service packs for Visual Studio. Unfortunately, our sources do not work smoothly with the freely available Visual C# Express. This is due to the fact that a major part of the application core, CrypWin, uses a commercial component and is therefore distributed only as a binary. The current version of Visual C# Express does not accept a binary file as a start-up project, and thus debugging is quite cumbersome. We hope to resolve this issue later in 2010 when the project is ported to Visual Studio 2010, but until then, we recommend using the full Visual Studio 2008 Professional version.

In order to run or compile our source code you will need at least the **Microsoft .NET 3.5 framework with Service Pack 1 (SP1)**. Usually the installation of Visual Studio also installs the .NET framework, but if you do not have the latest version, you can get it for free from [Microsoft's website](#). Once the framework has been installed, your development environment should be ready for our source code.

1.2 Accessing the Subversion (SVN) repository

Next you will need a way of accessing and downloading the source code. For the CrypTool 2 project we use **Subversion (SVN)** for version control, and hence you will need an SVN client, i.e. **TortoiseSVN** or the **svn commandline from cygwin**, to access our repository. It does not matter which client you use, but if SVN is new to you, we suggest using [TortoiseSVN](#), since it offers a handy, straightforward Windows Explorer integration. We will guide you through how to use TortoiseSVN, although you should be able to use any SVN client in a similar fashion.

1.2.1 Checking out the sources

First, download and install TortoiseSVN. This will require you to reboot your computer, but once it is back up and running, create a directory (for instance, *CrypTool2*) somewhere on your computer for storing the local working files. Right-click on this directory; now that TortoiseSVN has been installed, you should see a few new items in the context menu. Select *SVN Checkout*:

Figure 1.1: Selecting *SVN Checkout* from the context menu after installing TortoiseSVN.

A window will now appear that will ask you for the URL of the repository that you would like to access. Our code repository is stored at <https://www.cryptool.org/svn/CrypTool2/>, and this is what you should enter in the appropriate field. The *Checkout directory* should already be filled in correctly with your new folder, and you shouldn't need to change any other options.

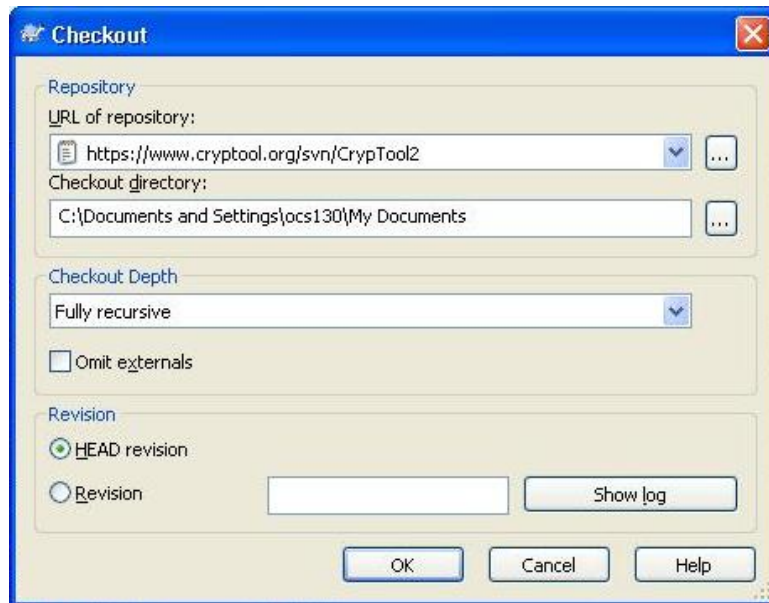

Figure 1.2: Checking out the CrypTool 2 repository.

Then just hit *OK*. You may be asked to accept a certificate (which you should accept), and you will certainly be asked for login information. If you are a registered developer, you should have already been given a username and password, and you should enter them here. (These are the same username and password that you can use for the [CrypTool 2 development wiki](#).) If you are a guest and just want to download the source code, you can use “anonymous” as the username and an empty password. Mark the checkbox for saving your credentials if you don't want to enter them every time you work with the repository. Finally, hit *OK*, and the whole CrypTool 2 repository will begin downloading into your chosen local directory.

Since CrypTool 2 is a collaborative project with many developers, changes are made to the repository rather frequently. You should maintain a current working copy of the files to ensure your interoperability with the rest of the project, and thus you should update to the latest version as often as possible. You can do this by right-clicking on any directory within the working files and choosing *SVN Update* from the context menu.

A TortoiseSVN tutorial can be found at <http://www.mind.ilstu.edu/research/robots/iris4/developers/svntutorial>.

1.2.2 Adjusting the SVN settings

If you are a registered developer, you can commit your file changes to the public CrypTool 2 repository. However, before you do, you should edit your settings to make sure that you only check in proper source code. First, bring up the TortoiseSVN settings window:

Figure 1.3: Getting to the TortoiseSVN settings.

The settings window will look something like this:

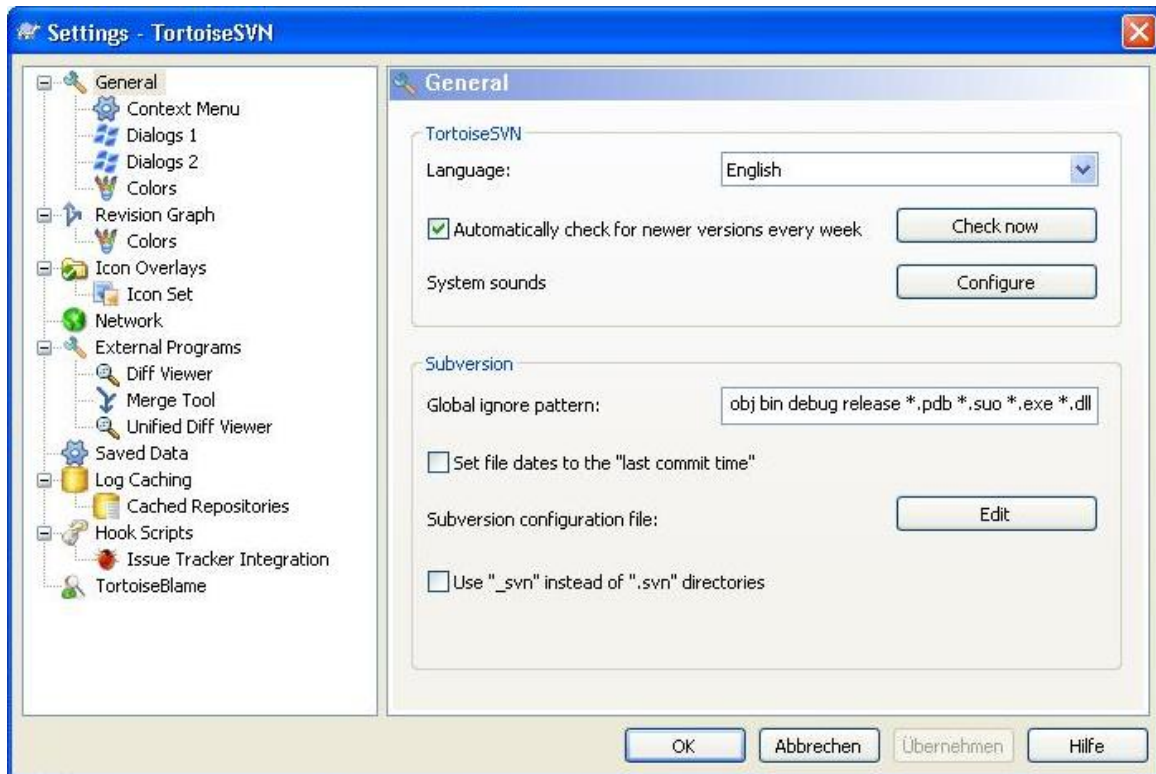

Figure 1.4: The TortoiseSVN settings window with the proper ignore pattern.

Then in the *Global ignore pattern* field, please enter the following text:

```
obj bin debug release *.pdb *.suo *.exe *.dll *.aux *.dvi *.log *.bak *.bbl *.blg *.user
```

You are free to also leave in any default pattern text or to write your own additions; this pattern serves simply to tell TortoiseSVN what kinds of files to ignore. You can now click *OK* to save your settings and close the window.

1.2.3 Committing your changes

Once you start writing code and developing your plugin, you should check your work into the project repository. If you are reading this document in sequence, you are probably not ready to do this, but while we are on the topic of SVN we will describe the process. To upload your changes, right-click on a directory within the working files that contains your changes and select *SVN Commit* from the context menu:

Figure 1.5: Selecting *SVN Commit* from the context menu.

When you commit your code, you can leave a comment to describe what you have changed. Please always provide *meaningful descriptions* of your updates. You can also select exactly which files you want to check in. The ignore pattern that we recommended should prevent most undesirable files from being in the list, but double-check to make sure everything you want to upload is included but nothing more. In general, you should never check in compiled and automatically generated files. For example, do not check in the entire *bin* and *obj* directories that Visual Studio generates. The server will reject your commits if you try to do so. You should commit your sources to our SVN repository as often as you can, but only commit code that successfully compiles and runs!

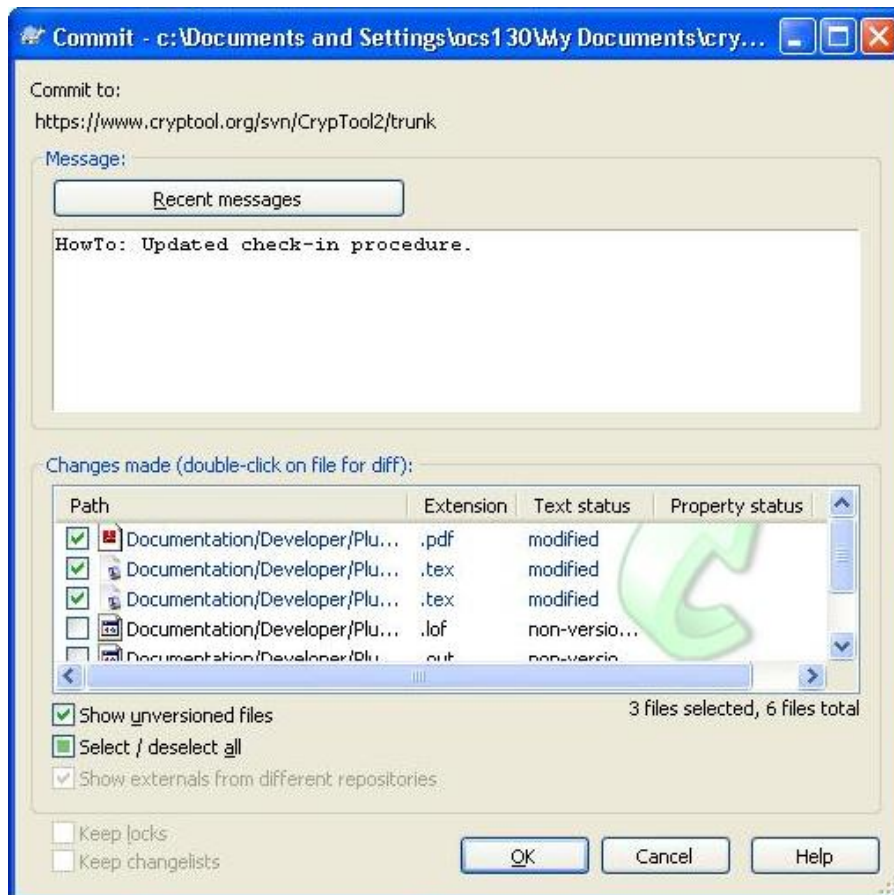

Figure 1.6: Providing comments for a commit.

You can use the SVN comments to link to your changes to a particular issue or bug ticket on the CrypTool 2 development wiki. (The list of active tickets can be found [here](#).) The following commands are supported (note that there are multiple variations of each command that are functionally identical):

closes, fixes:

The specified ticket will be closed and the contents of this commit message will be added to its notes.

references, refs, addresses, re:

The contents of this commit message will be added to the specified ticket's notes, but the status will be left unaltered.

You can apply the commands to multiple tickets simultaneously. The command syntax is as follows (again note that there are multiple variations that are functionally identical):

```
command #1
command #1, #2
command #1 & #2
command #1 and #2
```

You can also use more than one command in a message if necessary. For example, if you want to close tickets #10 and #12, and add a note to #17, you could type the following:

```
Changed blah and foo to do this or that. Fixes #10 and #12, and refs #17.
```

The comments can also be used to override the ignore pattern that the server is designed to block. However, please do not do this unless you are absolutely sure that you know what you are doing. If you are, you must use the *override-bad-extension* command and provide an explicit list of the file and directory names that you want to upload that need to override the ignore pattern. For example, if you want to check in a library file named *someLib.dll*, you must write something like the following:

```
This library is required by all developers, so I am adding it explicitly
to the repository.

override-bad-extension: someLib.dll
```

Note that any text after the colon and the whitespace will be treated as the file name. Therefore, do not use quotation marks and do not write any text after the file name.

1.3 Compiling the sources

By this point you should have checked out a copy of the entire CrypTool 2 repository. Compiling is pretty easy; just go to the *trunk* directory and open the **CrypTool 2.0.sln** Visual Studio solution. The Visual Studio IDE should open with all the working plugin components nicely arranged. If you are now starting Visual Studio for the first time, you will have to choose your settings. Just select either *most common* or *C#* — you can change this at any time later. On the right side is the project explorer, where you can see all the subprojects included in the solution. Look for the project **CrypWin.exe** there. Once you have found it, right-click on it and select *Set as StartUp Project* from the context menu. Next, go to the menu bar and select *Build* → *Build Solution*.

You may have to wait a while for the program to compile. Once it is finished, select *Debug* → *Start Debugging*. CrypTool 2 should now start for the first time with your own compiled code. Presumably you have not changed anything yet, but you now have your own build of all the components (with the exception of *CrypWin* and *AnotherEditor*, since they are available only as binaries). If the program does not compile or start correctly, please consult our [FAQ](#) and let us know if you found a bug.

If you are a **core developer**, hence somebody who can also compile CrypWin and AnotherEditor, you should use the **CrypTool 2.0.sln** solution from the *trunk*|*CoreDeveloper* directory (which will *not* be visible to you if you are not a core developer). As a core developer, be aware that when you compile, you **change the CrypWin.exe** that is visible to everybody else. Thus, when committing to the repository, please make sure you *really* want to check in a new binary. Core developers can also build a new setup and publish it as beta release on the website. This process is explained in the wiki at <https://www.cryptool.org/trac/CrypTool2/wiki/BuildSetup>.

2 Plugin Implementation

In this chapter we provide step-by-step instructions for implementing your own CrypTool 2 plugin. The given instructions refer primarily to the usage of **Microsoft Visual Studio Professional 2008**, so before starting you should have a copy of the program installed on your computer.

2.1 Downloading the example and template

We will use the **Caesar cipher** (also known as the **shift cipher**) as an example throughout this chapter. If you did not download the entire CrypTool 2 source code as described in Section 1.2.1, you can still get a copy of the source code for the Caesar algorithm referenced throughout this guide from the following location:

username: anonymous

password: (not required)

<https://www.cryptool.org/svn/CrypTool2/trunk/CrypPlugins/Caesar/>

We have also created a Visual Studio plugin **template** to help with the development of new plugins. Using this template is strongly recommended over copying and pasting code from this document! The template and a short readme can be found here:

<http://cryptool2.vs.uni-due.de/index.php?page=33&lm=3>

2.2 Creating a new project

To begin, open Visual Studio, go to the menu bar and select *File* → *New* → *Project...* The following window will appear:

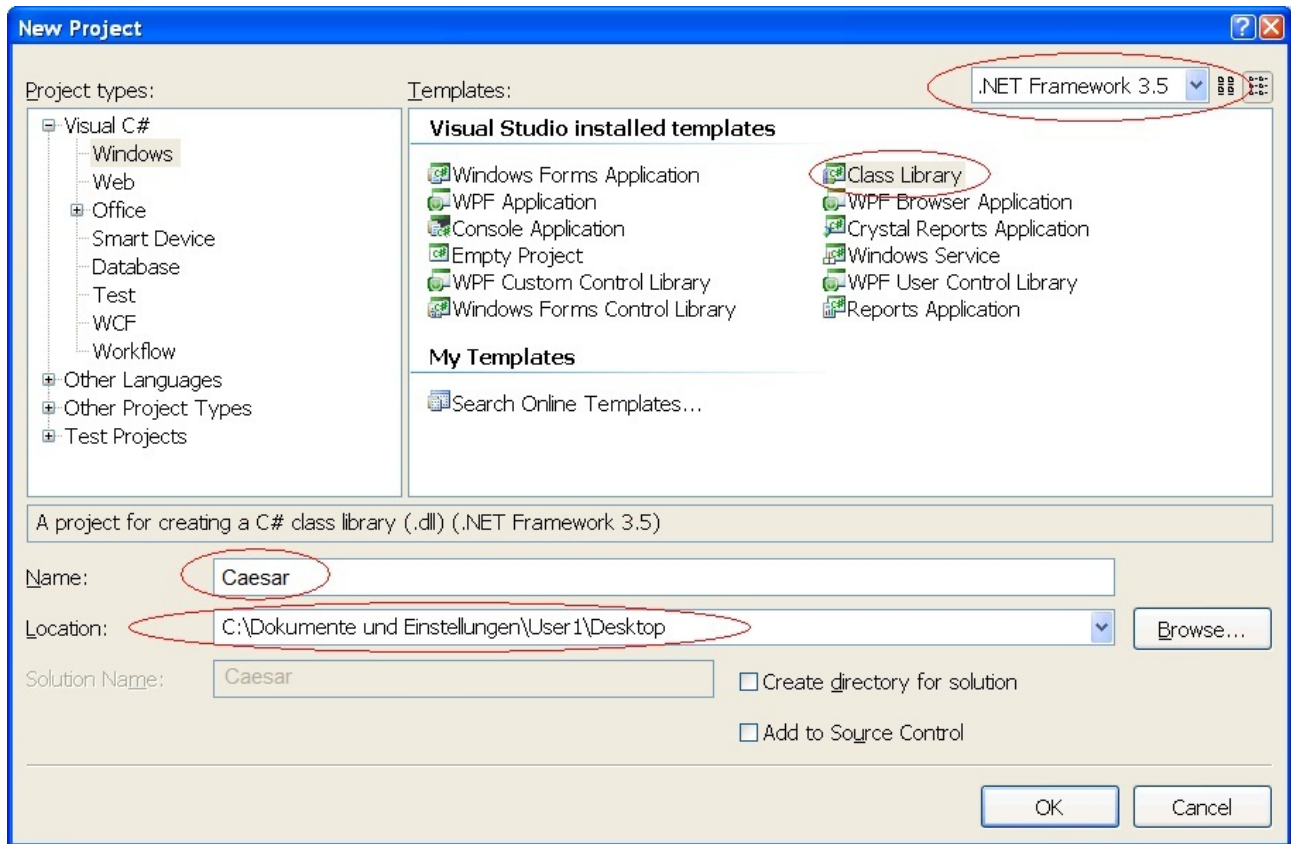

Figure 2.1: Creating a new Visual Studio project.

Select **.NET-Framework 3.5** as the target framework. Then choose *Class Library* as the default template, as this will build the project for your plugin as a DLL file. Give the project a unique and meaningful name (such as *Caesar* in our case), and choose a location to save it to. Select the subdirectory *CrypPlugins* from your SVN trunk as the location. Finally, confirm by pressing the *OK* button. Note that creating a new project in this manner also creates a new solution into which the project is placed. At this point, your Visual Studio solution should look like this:

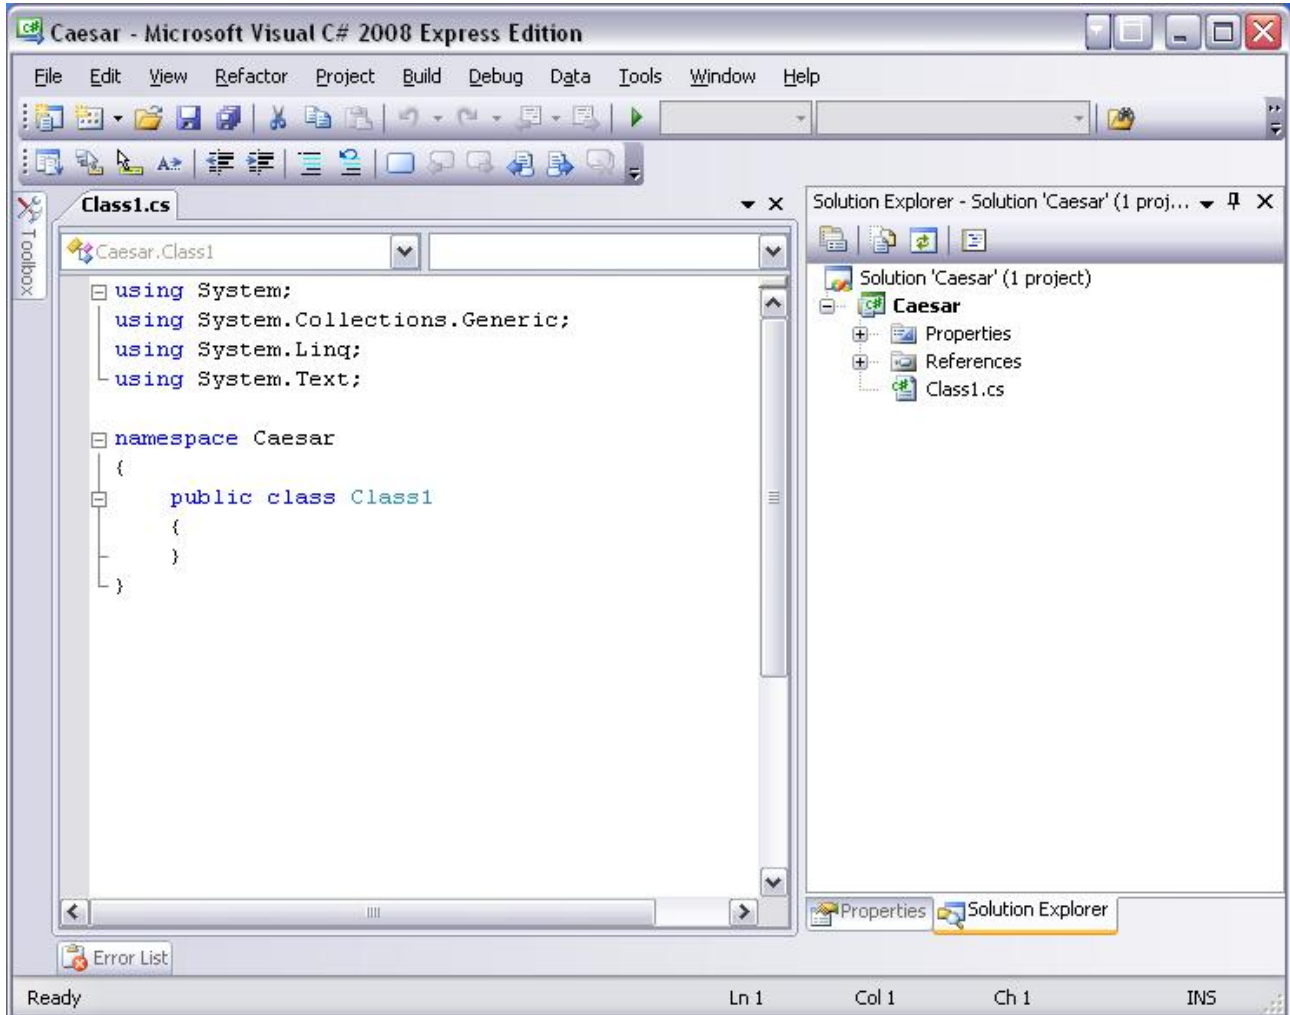

Figure 2.2: A newly created solution and project.

2.3 Interface selection

To include our new plugin in the CrypTool 2 application, we must first add a reference to the CrypTool 2 library *CrypPluginBase.dll*, where all the necessary CrypTool 2 plugin interfaces are declared.

Figure 2.3: Adding a new reference.

Right-click in the Solution Explorer on the *Reference* item and choose *Add Reference*. A window like the following should appear:

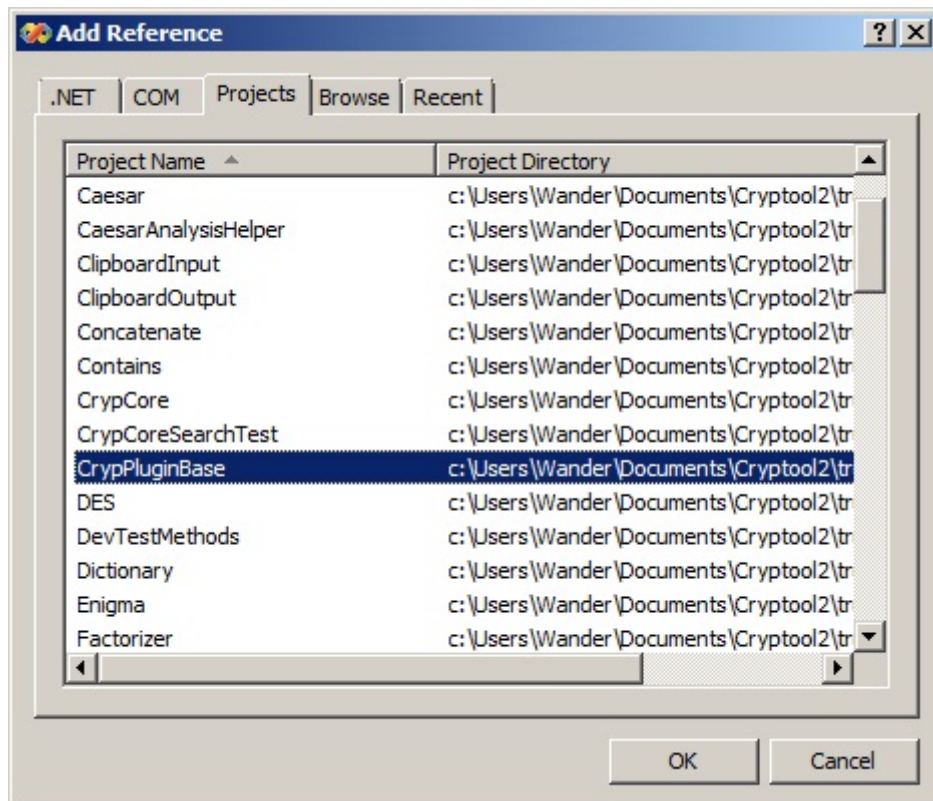

Figure 2.4: Adding a reference to the CrypPluginBase source code.

Unless you have created your new project in the same CrypTool 2 solution, you probably will not be able to select the library directly as seen above in Figure 2.4; instead you can browse for the binary DLL as seen below in Figure 2.5. Click on the *Browse* tab and navigate to the folder in which you downloaded the CrypTool 2 project. Within that folder, go to `|CrypPluginBase|bin|Debug` and select the file *CrypPluginBase.dll*. The library reference can then be added by double clicking the file or pressing the *OK* button.

Figure 2.5: Browsing for a reference.

Besides *CrypPluginBase* you will need to add three Windows assembly references to provide the necessary namespaces for the user control functions *Presentation* and *QuickWatchPresentation*. This can be done in a similar manner as before with the *CrypPluginBase* reference, but by selecting the *.NET* tab and searching for the references there. Select the following .NET components:

- *PresentationCore*
- *PresentationFramework*
- *WindowsBase*

After these additions, your reference tree view should look like this:

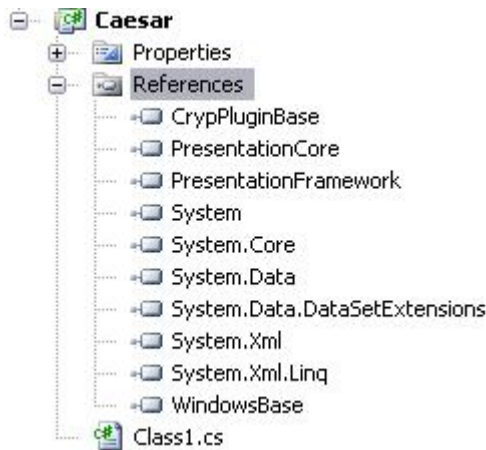

Figure 2.6: A reference tree with the essential components.

If your plugin will require other additional libraries, you can add them in the same way.

2.4 Modifying the project properties

It is important to make two small changes to your plugin's assembly data to make sure that it will be imported correctly into CrypTool 2. Go to the Solution Explorer and open *AssemblyInfo.cs*, which can be found in the *Properties* folder. Make the following two changes:

- Change the attribute *AssemblyVersion* to have the value "2.0.*", and
- Comment out the attribute *AssemblyFileVersion*.

This section of your assembly file should now look something like this:

```
1 [assembly: AssemblyVersion("2.0.*")]
2 //[assembly: AssemblyFileVersion("1.0.0.0")]
```

2.5 Creating classes for the algorithm and its settings

In the next step we will create two classes. The first class will be the main driver; we will call ours *Caesar* since that is the name of the cipher that it will implement. In our case, this class has to inherit from *IEncryption* because it will be an encryption plugin. If it was instead a hash plugin, this class should inherit from *IHash*. The second class will be used to store setting information for the plugin, and thus we will name ours *CaesarSettings*. It will need to inherit from *ISettings*.

2.5.1 Creating a class for the algorithm

When starting a new project, Visual Studio automatically creates a class named *Class1.cs*. Since this is a rather non-descriptive name, we will change it. In our example, it will be *Caesar.cs*. There are two ways to change the name:

- Rename the existing class, or
- Delete the existing class and create a new one.

Both options will achieve the same results. We will guide you through the second method. First, delete *Class1.cs*.

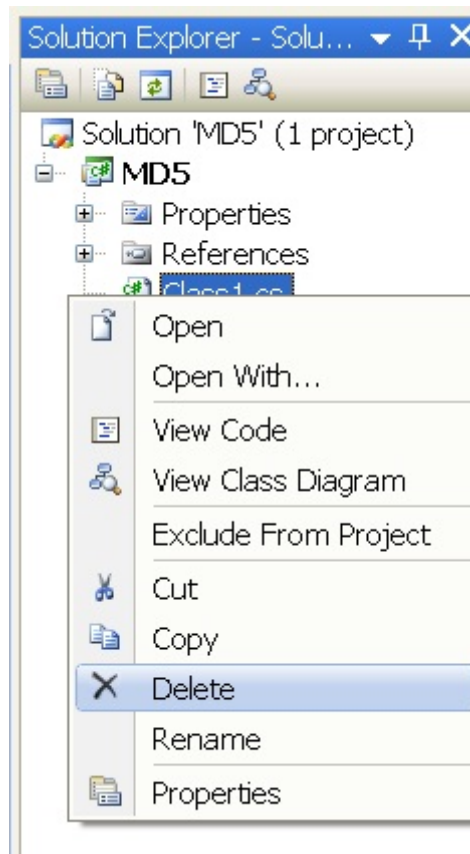

Figure 2.7: Deleting a class.

Then right-click on the project item (in our case, *Caesar*) and select *Add* → *Class...*:

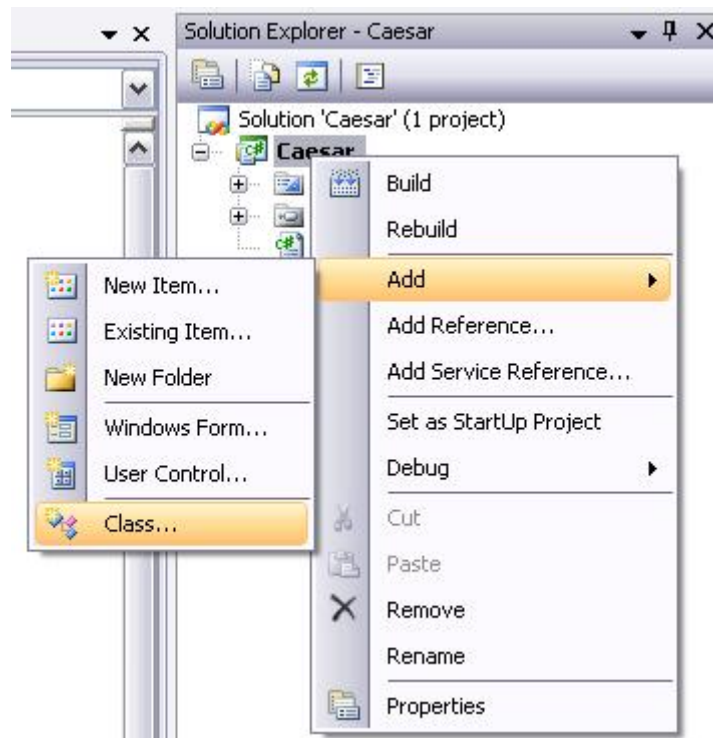

Figure 2.8: Adding a new class.

Finally, give your class a unique name. We will call our class *Caesar.cs* and define it as public so that it will be available to other classes.

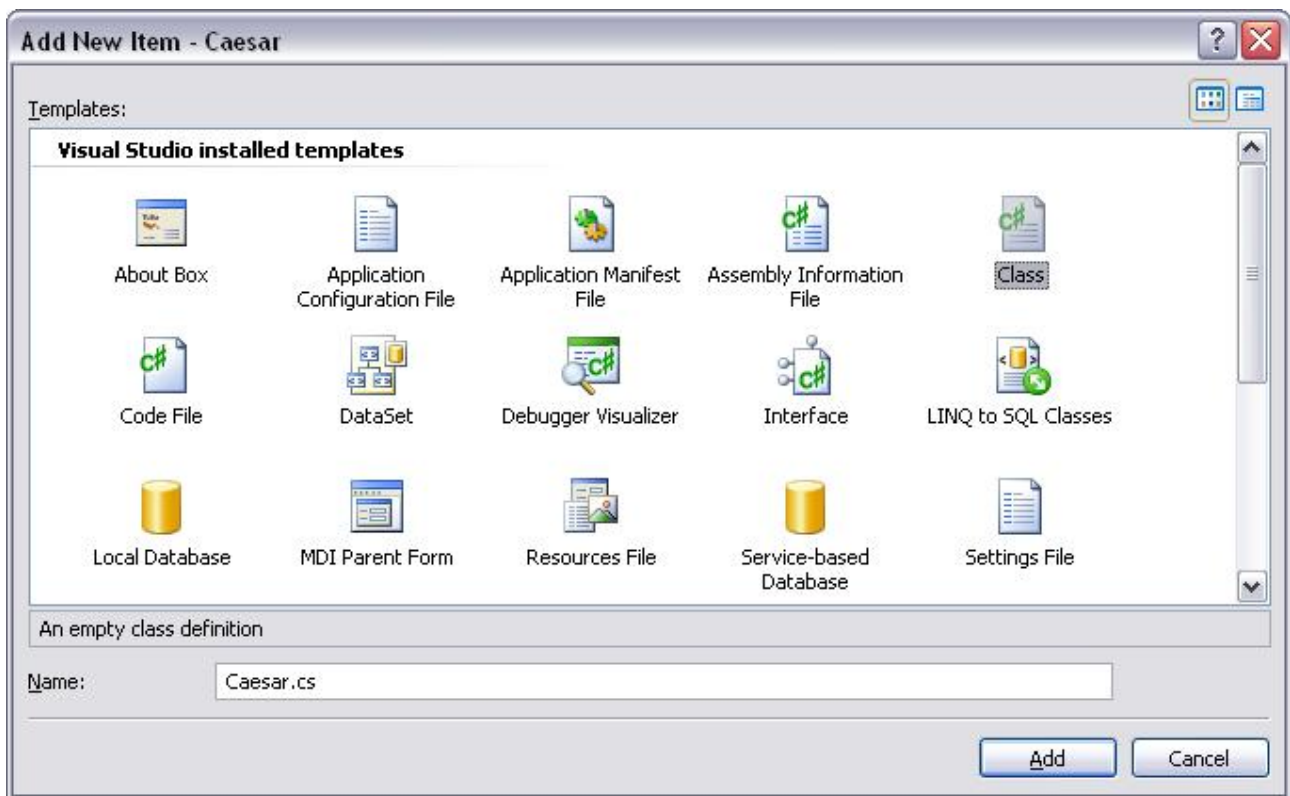

Figure 2.9: Naming the new class.

Note that Visual Studio will automatically generate a very basic code outline for the new class. In our example, we will not use the all the namespaces that are automatically imported, so you can delete the line `using System.Linq;`.

2.5.2 Creating a settings class

Add a second public class in the same way. We will call the class *CaesarSettings*. The settings class will store the necessary information about controls, captions, descriptions and default parameters (e.g. for key settings, alphabets, key length and type of action) to build the **TaskPane** in the **CrypTool** application.

Below is an example of what a completed TaskPane for the existing Caesar plugin in CrypTool 2 looks like:

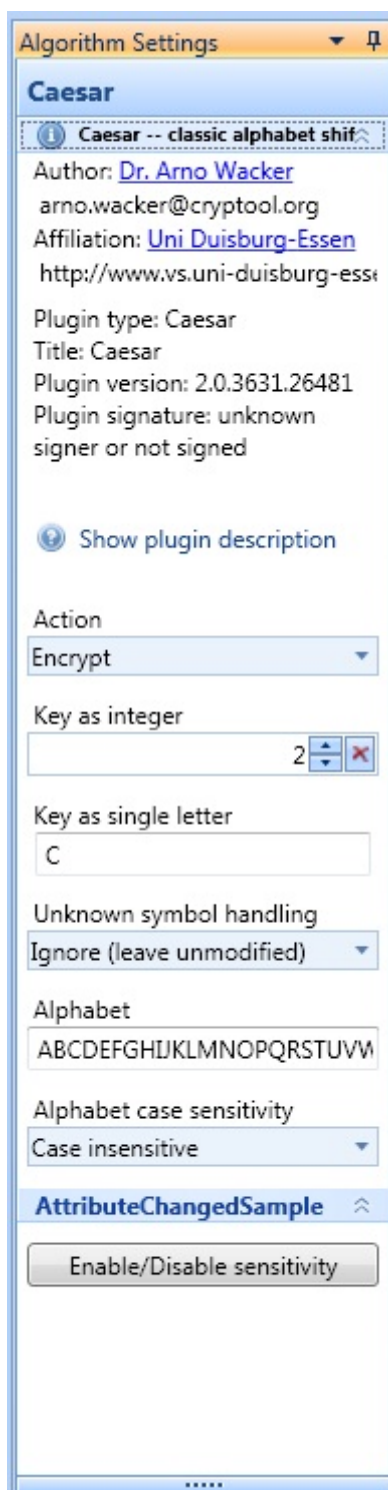

Figure 2.10: The completed TaskPane for the existing Caesar plugin.

2.5.3 Adding the namespaces and inheritance sources for the Caesar class

Open the *Caesar.cs* file by double clicking on it in the Solution Explorer. To include the necessary namespaces in the class header, use the `using` statement followed by the name of the desired namespace. The CrypTool 2 API provides the following namespaces:

- *Cryptool.PluginBase* — contains interfaces such as *IPlugin*, *IHash*, and *ISettings*, as well as attributes, enumerations, delegates and extensions.
- *Cryptool.PluginBase.Analysis* — contains interfaces for cryptanalysis plugins (such as *Stream Comparator*).
- *Cryptool.PluginBase.Control* — contains global interfaces for the *IControl* feature for defining custom controls.
- *Cryptool.PluginBase.Cryptography* — contains interfaces for encryption and hash algorithms such as AES, DES and MD5.
- *Cryptool.PluginBase.Editor* — contains interfaces for editors that can be implemented in CrypTool 2, such as the default editor.
- *Cryptool.PluginBase.Generator* — contains interfaces for generators, including the random input generator.
- *Cryptool.PluginBase.IO* — contains interfaces for input, output and the *CryptoolStream*.
- *Cryptool.PluginBase.Miscellaneous* — contains assorted helper classes, including *GuiLogMessage* and *PropertyChanged*.
- *Cryptool.PluginBase.Resources* — used only by CrypWin and the editor; not necessary for plugin development.
- *Cryptool.PluginBase.Tool* — contains an interface for all external tools implemented by CrypTool 2 that do not entirely support the CrypTool 2 API.
- *Cryptool.PluginBase.Validation* — contains interfaces for validation methods, including regular expressions.

In our example, the Caesar algorithm necessitates the inclusion of the following namespaces:

- *Cryptool.PluginBase* — to implement *ISettings* in the *CaesarSettings* class.
- *Cryptool.PluginBase.Cryptography* — to implement *IEncryption* in the *Caesar* class.
- *Cryptool.PluginBase.IO* — to use *CryptoolStream* for data input and output.
- *Cryptool.PluginBase.Miscellaneous* — to use the CrypTool event handler.

It is important to define a new default namespace for our public class (*Caesar*). In CrypTool 2 the standard namespace convention is *Cryptool.[name of class]*. Therefore our namespace will be defined as *Cryptool.Caesar*.

At this point, the source code should look like the following:

```

1 using System;
2 using System.Collections.Generic;
3 using System.Text;
4
5 //required Cryptool namespaces
6 using Cryptool.PluginBase;
7 using Cryptool.PluginBase.Cryptography;
8 using Cryptool.PluginBase.IO;
9 using Cryptool.PluginBase.Miscellaneous;
10
11 namespace Cryptool.Caesar
12 {
13     public class Caesar
14     {
15     }
16 }

```

Next we should let the *Caesar* class inherit from *IEncryption* by making the following alteration:

```

1 namespace Cryptool.Caesar
2 {
3     public class Caesar : IEncryption
4     {
5     }
6 }

```

2.5.4 Adding interface functions to the Caesar class

You may notice an underscore underneath the *I* in *IEncryption*. Move your mouse over it, or place the cursor on it and press *Shift+Alt+F10* and the following submenu should appear:

Figure 2.11: An inheritance submenu.

Select the item *Implement interface 'IEncryption'*. Visual Studio will automatically generate all the interface members necessary for interaction with the Cryptool 2 core. (This step will save you a lot of typing!)

Your code should now look like this:

```

1 using System;
2 using System.Collections.Generic;
3 using System.Text;
4
5 using Cryptool.PluginBase;
6 using Cryptool.PluginBase.Cryptography;
7 using Cryptool.PluginBase.IO;
8 using Cryptool.PluginBase.Miscellaneous;
9
10 namespace Cryptool.Caesar
11 {
12     public class Caesar : IEncryption
13     {
14         #region IPlugin Members
15
16         public void Dispose()
17         {
18             throw new NotImplementedException();
19         }
20
21         public void Execute()
22         {
23             throw new NotImplementedException();
24         }
25
26         public void Initialize()
27         {
28             throw new NotImplementedException();
29         }
30
31         public event GuiLogNotificationEventHandler
32             OnGuiLogNotificationOccured;
33
34         public event PluginProgressChangedEventHandler
35             OnPluginProgressChanged;
36
37         public event StatusChangedEventHandler OnPluginStatusChanged;
38
39         public void Pause()
40         {
41             throw new NotImplementedException();
42         }
43
44         public void PostExecution()
45         {
46             throw new NotImplementedException();
47         }
48
49         public void PreExecution()

```

```

48         {
49             throw new NotImplementedException();
50         }
51
52         public System.Windows.Controls.UserControl Presentation
53         {
54             get { throw new NotImplementedException(); }
55         }
56
57         public System.Windows.Controls.UserControl
58             QuickWatchPresentation
59         {
60             get { throw new NotImplementedException(); }
61         }
62
63         public ISettings Settings
64         {
65             get { throw new NotImplementedException(); }
66         }
67
68         public void Stop()
69         {
70             throw new NotImplementedException();
71         }
72
73         #endregion
74
75         #region INotifyPropertyChanged Members
76
77         public event System.ComponentModel.PropertyChangedEventHandler
78             PropertyChanged;
79
80         #endregion
81     }
82 }

```

2.5.5 Adding the namespace and interfaces to the CaesarSettings class

Let's now take a look at the second class in our example, *CaesarSettings*, by double-clicking on the *CaesarSettings.cs* file in the Solution Explorer. First, we need to again include the *Cryptool.PluginBase* namespace to the class header. Then we must let the settings class inherit from *ISettings* in the same manner as was done with the Caesar class. Visual Studio will again automatically generate code from the *CrypTool* interface as seen below. (In this case, we can remove the `using System.Collections.Generic;`, `using System.Linq;`, and `using System.Text;` lines, as we will not use those references.)

```

1 using System;
2
3 using Cryptool.PluginBase;
4
5 namespace Cryptool.Caesar
6 {
7     public class CaesarSettings : ISettings
8     {
9         #region ISettings Members
10
11         public bool HasChanges
12         {
13             get
14             {
15                 throw new NotImplementedException();
16             }
17             set
18             {
19                 throw new NotImplementedException();
20             }
21         }
22
23         #endregion
24
25         #region INotifyPropertyChanged Members
26
27         public event System.ComponentModel.PropertyChangedEventHandler
            PropertyChanged;
28
29         #endregion
30     }
31 }

```

2.5.6 Adding controls to the CaesarSettings class

The settings class is used to populate the TaskPane in the CrypTool 2 application so that the user can modify the plugin settings at will. Thus we will need to implement some controls, such as buttons and text boxes, to allow for the necessary interaction. If you will be implementing an algorithm that does not have any user-defined settings (i.e. a hash function), then this class can be left mostly empty; you will, however, still have to modify the *HasChanges* property to avoid a *NotImplementedException*. The following code demonstrates the modifications necessary to create the backend for the TaskPane for our Caesar algorithm. You can also look at the source code of other CrypTool 2 plugins for examples of how to create the TaskPane backend.

```

1 using System;
2 using System.ComponentModel;
3 using System.Windows;
4 using System.Windows.Controls;
5

```

```

6 using Cryptool.PluginBase;
7
8 namespace Cryptool.Caesar
9 {
10     public class CaesarSettings : ISettings
11     {
12         #region Public Caesar specific interface
13
14         /// <summary>
15         /// This delegate is used to send log messages from
16         /// the settings class to the Caesar plugin.
17         /// </summary>
18         public delegate void CaesarLogMessage(string msg,

364             {
365                 TaskPaneAttributeChanged(this, new
366                     TaskPaneAttributeChangedEventArgs(new
367                         TaskPaneAttributeContainer("AlphabetCase", Visibility.
368                             Collapsed)));
369             }
370         }
371     }
372     #endregion TaskPaneAttributeChanged (Sample)
373 }

```

2.6 Adding an icon to the Caesar class

Before we go back to the code of the Caesar class, we have to add an icon to our project, which will be shown in the CrypTool 2 **ribbon bar** and **navigation pane**. As there is currently no default, it is mandatory to add an icon. (It is planned to include a default icon in future versions.)

For testing purposes you can just create a simple black and white PNG image with any graphics editing program, such as MS Paint or Paint.NET. The proper image size is 40x40 pixels, but since the image will be rescaled if necessary, any size is technically acceptable.

Once you have saved your icon, you should add it directly to the project or to a subdirectory with it. In the project solution, we created a new folder named *Images*. This can be done by right-clicking on the project item (*Caesar* in our example) and selecting *Add* → *New Folder*. The icon can be added to this folder (or to the project directly, or to any other subdirectory) by right-clicking on the folder and selecting *Add* → *Existing Item*.

Figure 2.12: Adding an existing item.

A new window will then appear. Select *Image Files* as the file type and select your newly-created icon for your plugin.

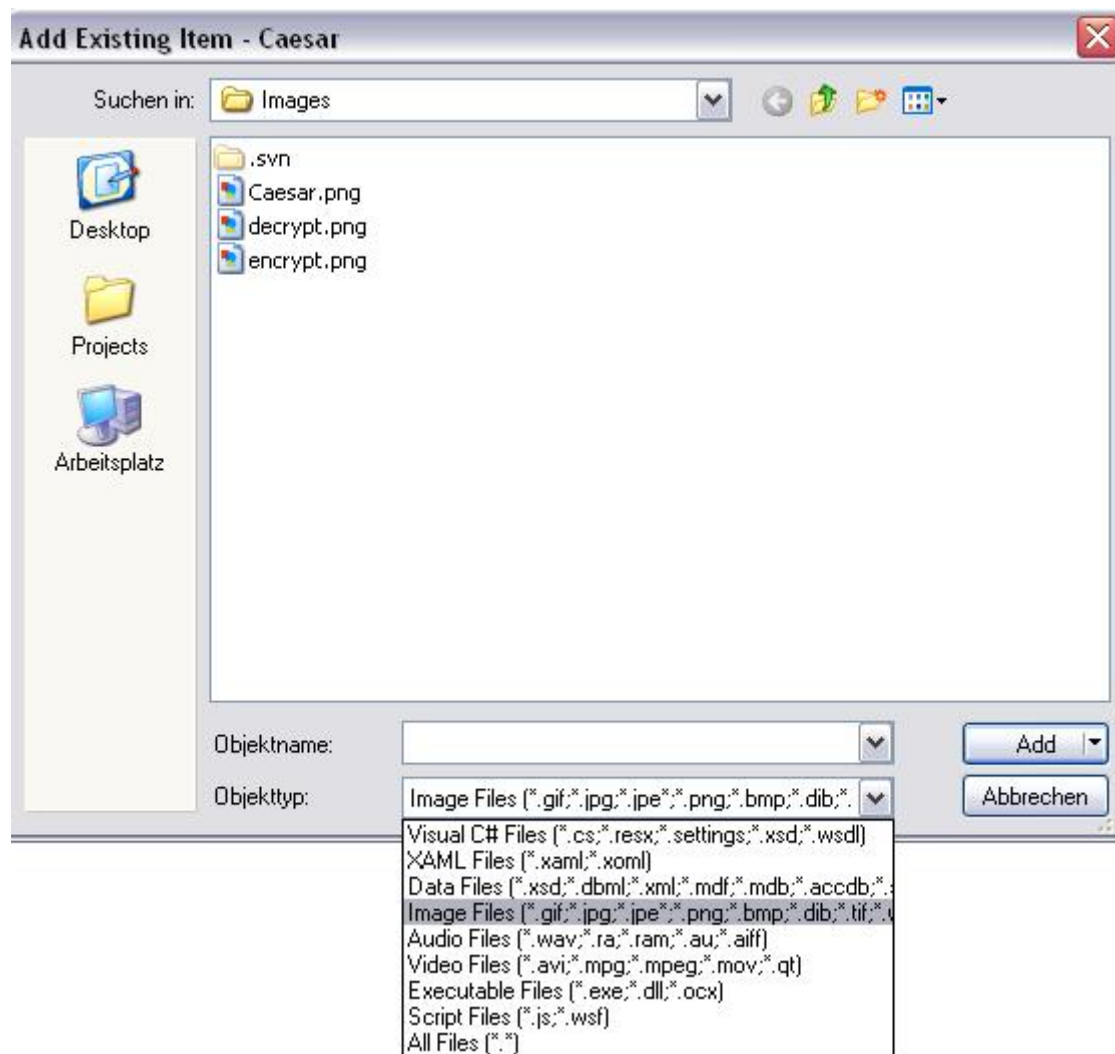

Figure 2.13: Selecting the image file.

Finally, we must set the icon as a *Resource* to avoid including the icon as a separate file. Right-click on the icon and select *Properties* as seen below.

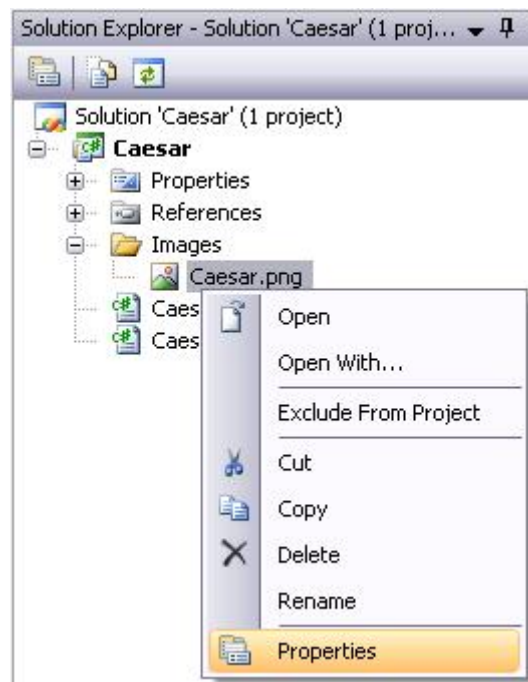

Figure 2.14: Selecting the image properties.

In the *Properties* panel, set the *Build Action* to *Resource*.

Figure 2.15: Selecting the icon's build action.

2.7 Defining the attributes of the Caesar class

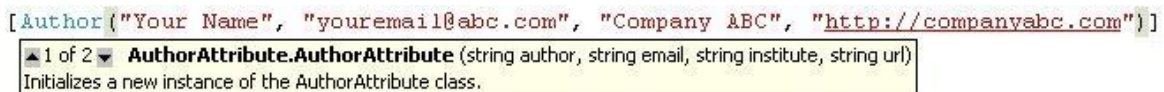

Now let's go back to the code of the Caesar class (the *Caesar.cs* file in our example). The first thing we will do is define the attributes of our class. These attributes are used to provide additional information for the CrypTool 2 environment. If they are not properly defined, your plugin won't show up in the application user interface, even if everything else is implemented correctly.

Attributes are used for declarative programming and provide metadata that can be added to the existing .NET metadata. CrypTool 2 provides a set of custom attributes that are used to mark the different parts of your plugin.

These attributes can be defined anywhere within the *Cryptool.Caesar* namespace, but customarily they are defined right before the class declaration.

2.7.1 The *[Author]* attribute

The *[Author]* attribute is optional, meaning that we are not required to define it. The attribute can be used to provide additional information about the plugin developer (or developers, as the case may be). This information will appear in the TaskPane, as for example in Figure 2.10. We will define the attribute to demonstrate how it should look in case you want to use it in your plugin.

```
[Author("Your Name", "youremail@abc.com", "Company ABC", "http://comanyabc.com")]
```

1 of 2 **AuthorAttribute.AuthorAttribute** (string author, string email, string institute, string url)
Initializes a new instance of the AuthorAttribute class.

Figure 2.16: The definition for the *[Author]* attribute.

As can be seen above, the author attribute takes four elements of type string. These elements are:

- *Author* — the name of the plugin developer.
- *Email* — the email address of the plugin developer, should he or she wish to be available for contact.
- *Institute* — the organization, company or university with which the developer is affiliated.
- *URL* — the website of the developer or of his or her institution.

All of these elements are optional; the developer can choose what information will be published. Unused elements should be set to **null** or an empty string.

2.7.2 The *[PluginInfo]* attribute

The second attribute, *[PluginInfo]*, provides necessary information about the plugin, and is therefore mandatory. The information defined in this attribute appears in the caption and tool tip window. The attribute is defined as follows:

```
[PluginInfo("Cryptool.Caesar.Resources.res", false, "pluginName", "pluginToolTip",
    "Caesar/DetailedDescription/Description.xml", "Caesar/Images/Caesar.png",
    "Caesar/Images/encrypt.png", "Caesar/Images/decrypt.png")]
```

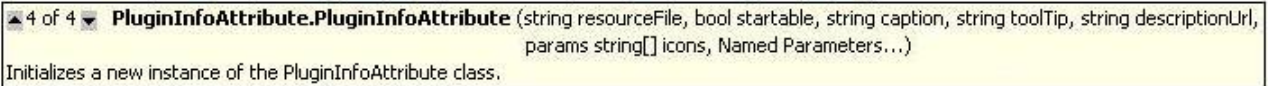

Figure 2.17: The definition for the *[PluginInfo]* attribute.

This attribute has the following parameters:

- *Resource File* — the relative path of the associated resource file (if the plugin makes use of one). These files are used primarily to provide multilingual support for the plugin, although this is currently a work in progress. This element is optional.
- *Startable* — a flag that should be set to **true** only if the plugin is an input generator (i.e. if your plugin only has outputs and no inputs). In all other cases this should be set to **false**. This flag is important — setting it incorrectly will result in unpredictable results. This element is mandatory.
- *Caption* — the name of the plugin, or, if using a resource file, the name of the field in the file with the caption data. This element is mandatory.
- *ToolTip* — a description of the plugin, or, if using a resource file, the name of the field in the resource file with the toolTip data. This element is optional.
- *DescriptionURL* — the local path of the description file (e.g. XAML file). This element is optional.
- *Icons* — an array of strings to define all the paths of the icons used in the plugin (i.e. the plugin icon described in Section 2.6). This element is mandatory.

Unused elements should be set to **null** or an empty string.

There are a few limitations and bugs that still exist in the *[PluginInfo]* attribute that will be resolved in a future version. First, it is possible to use the plugin without setting a caption, although this is not recommended, and future versions of the plugin will fail to load without a caption. Second, a zero-length toolTip string currently causes the toolTip to appear as an empty box in the application. Third, the toolTip and description do not currently support internationalization and localization. Since the precise formulation and functionality of this attribute is still being developed, it is recommended to view other plugins for examples.

In our example, the *resourceFile* parameter should be set to *Cryptool.Caesar.Resource.res*. This file will be used to store the label and caption text to support multilingualism.

The second parameter, *startable*, should be set to **false**, because our encryption algorithm is not an input generator.

The next two parameters are necessary to define the plugin's name and description. Since we are using a resource file, we should place here the names of the resource fields that contain the caption and toolTip. (We could also just write simple text strings instead of using outsourced references.)

The *DescriptionURL* element defines the location path of the description file. The parameter is composed in the format `<assembly name>/<file name>` or, if you want to store your description files in a separate folder (as in our case), `<assembly name>/<path>/<file name>`. The description file must be an XAML file. In our case, we shall create a folder named *DetailedDescription* in which to store our XAML file with any necessary images. Our folder structure now looks as follows:

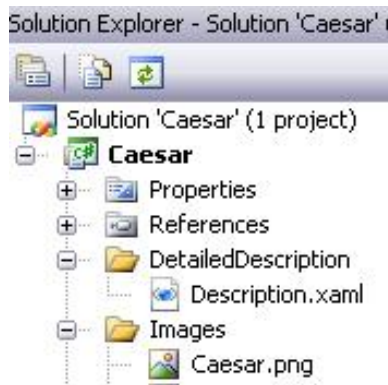

Figure 2.18: The folder structure as seen in the Solution Explorer.

Once a detailed description has been written in the XAML file, it can be accessed in the CrypTool 2 application by right-clicking on the plugin icon in the workspace and selecting *Show description*.

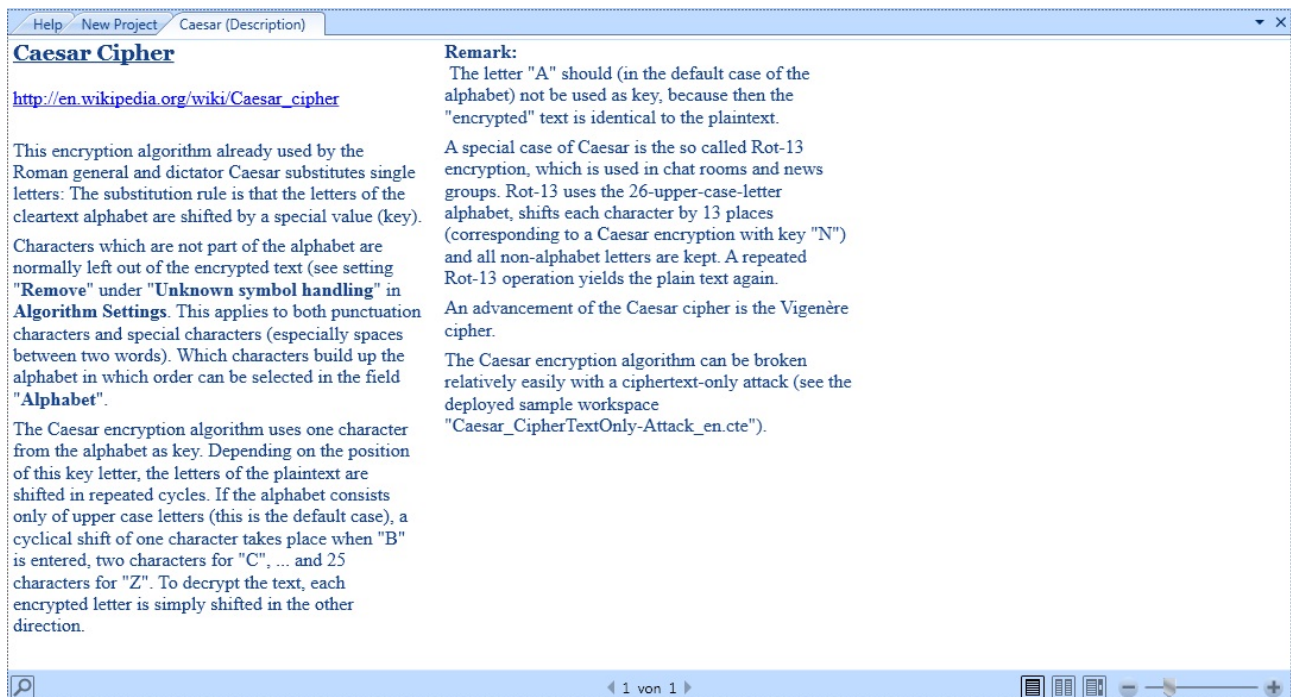

Figure 2.19: A detailed description provided through an XAML file.

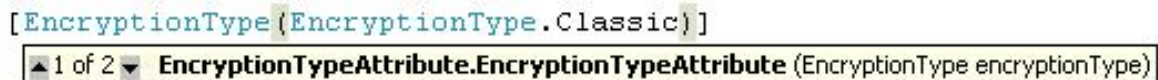

The last parameter tells CrypTool 2 the names of the provided icons. This parameter is an array composed of strings in the format `<assembly name>/<file name>` or `<assembly name>/<path>/<file name>`.

The first and most important icon is the plugin icon, which will be shown in CrypTool 2 in the ribbon bar and navigation pane. Once the icon has been added to the project as described in Section 2.6, we must accordingly tell CrypTool 2 where to find the icon. This can be seen above in Figure 2.17.

If your plugin will use additional icons, you should define the paths to each of them by adding the path strings to the `[PluginInfo]` attribute parameter list, each separated by a comma. We have added two further icons for the context menu in the CrypTool 2 workspace. (If you choose to add more icons, don't forget to add the icons to your solution.)

2.7.3 The `[EncryptionType]` attribute

The third and last attribute, `[EncryptionType]`, is needed to tell CrypTool 2 what type of plugin we are creating. CrypTool 2 uses this information to place the plugin in the correct group in the navigation pane and ribbon bar. In our example, since Caesar is a classical algorithm, we will define the attribute as follows:

```
[EncryptionType(EncryptionType.Classic)]
```

▲ 1 of 2 ▼ EncryptionTypeAttribute.EncryptionTypeAttribute(EncryptionType encryptionType)

Figure 2.20: A defined `[EncryptionType]` attribute.

The possible values of the `[EncryptionType]` attribute are as follows:

- *Asymmetric* — for asymmetrical encryption algorithms, such as RSA.
- *SymmetricBlock* — for block cipher algorithms, such as DES, AES and Twofish.
- *SymmetricStream* — for stream cipher algorithms, such as RC4, Rabbit and SEAL.
- *Hybrid* — for algorithms which are actually a combination of several algorithms, such as algorithms in which the data is encrypted symmetrically and the encryption key asymmetrically.
- *Classic* — for classical encryption or hash algorithms, such as Caesar or MD5.

2.8 Defining the private variables of the settings in the Caesar class

The next step is to define some private variables that are needed for the settings, input, and output data. In our example, this will look like the following:

```
1 public class Caesar : IEncryption
2 {
3     #region Private variables
4     private CaesarSettings settings;
5     private string inputString;
6     private string outputString;
7     private enum CaesarMode { encrypt, decrypt };
8     private List<CrypToolStream> listCrypToolStreamsOut = new List<
        CrypToolStream>();
9     #endregion
```

If your algorithm deals with long strings of code, it is recommended to use the *CryptoolStream* data type. This was designed for input and output between plugins and to handle large amounts of data. To use the native CrypTool stream type, include the namespace *Cryptool.PluginBase.IO* with a `using` statement as explained in Section 2.5.3.

Our example makes use of the following private variables:

- `CaesarSettings settings` — required to implement the `IPlugin` interface properly.
- `string inputString` — string from which to read the input data.
- `string outputString` — string to which to save the output data.
- `enum CaesarMode` — used to select either encryption or decryption.
- `List<CryptoolStream> listCryptoolStreamsOut` — a list of all streams created by the plugin, which helps to perform a clean dispose.

2.9 Implementing the interfaces in the Caesar class

2.9.1 Connecting the settings class

The next major step is to write out our implementations of the interfaces. First we will add a constructor to our class. We will use this to create an instance of our settings class and a function to handle events:

```

1 public Caesar()
2 {
3     this.settings = new CaesarSettings();
4     this.settings.LogMessage += GuiLogMessage;
5 }

```

Secondly, we must implement the *Settings* property declared in the interface. An outline of this property should have been automatically generated by implementing the interface (see Section 2.5.4); just edit it appropriately to communicate with your settings class as we have done here:

```

1 public ISettings Settings
2 {
3     get { return (ISettings)this.settings; }
4     set { this.settings = (CaesarSettings)value; }
5 }

```

2.9.2 The input/output attributes

Next we will define five properties, each with an appropriate attribute, to be used for input and output. The attributes are necessary to tell CrypTool 2 whether the properties are used for input or output and to provide the plugin with external data.

The attribute that we will use for each property is called *[PropertyInfo]* and it consists of the following elements:

- *direction* — defines whether this property is an input or output property, e.g. whether it reads input data or writes output data. The possible values are:
 - `Direction.Input`
 - `Direction.Output`
- *caption* — the caption for the property displayed over the input or output arrow of the icon after it has been placed in the editor; “Input stream” in the example below:

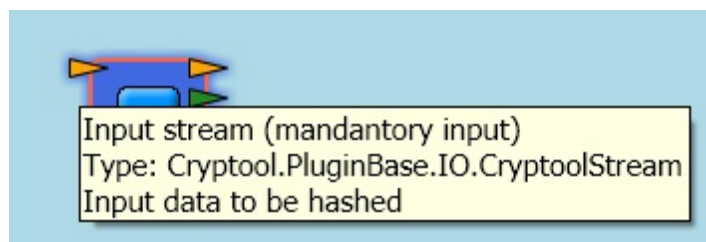

Figure 2.21: A possible property caption and toolTip.

- *toolTip* — the toolTip for the property displayed over the input or output arrow of the icon after it has been placed in the editor; “Input data to be hashed” in the example above.
- *descriptionUrl* — currently not used; fill it with `null` or an empty string.
- *mandatory* — this flag determines whether an input must be attached by the user to use the plugin. If set to `true`, an input connection will be required or else the plugin will not be executed in the workflow chain. If set to `false`, connecting an input is optional. As this only applies to input properties, if the direction has been set to `Direction.Output`, this flag will be ignored.
- *hasDefaultValue* — if this flag is set to `true`, CrypTool 2 will assume that the property has a default input value that does not require user input.
- *displayLevel* — determines in which display levels your property will be shown in CrypTool 2. These are used to hide more advanced item from less-experienced users; a beginner using the corresponding display level will not see the properties marked as any other level, but a professional using the appropriate display level will have access to everything. These levels are as follows:
 - `DisplayLevel.Beginner`
 - `DisplayLevel.Experienced`
 - `DisplayLevel.Expert`
 - `DisplayLevel.Professional`

- *quickWatchFormat* — determines how the content of the property will be shown in the quickwatch perspective. CrypTool 2 accepts the following quickwatch formats:
 - `QuickWatchFormat.Base64`
 - `QuickWatchFormat.Hex`
 - `QuickWatchFormat.None`
 - `QuickWatchFormat.Text`

Figure 2.22: A quickwatch display in hexadecimal.

- *quickWatchConversionMethod* — this is used to indicate a conversion method; most plugins do not need to convert their data and thus should use a `null` value here. The quickwatch function uses the default system encoding to display data, so if your data is in another format, such as UTF-16 or Windows-1250, you should provide here the name of a conversion method as string. The header for such a method should look something like the following:

```
1 object YourMethodName(string PropertyNameToConvert)
```

2.9.3 Defining the input/output properties

The first of the five properties that we will define is *InputString*. This is used to provide our plugin with the data to be encrypted or decrypted:

```
1 [PropertyInfo(Direction.InputData, "Text input", "Input a string to be
   processed by the Caesar cipher", "", true, false, DisplayLevel.
   Beginner, QuickWatchFormat.Text, null)]
2 public string InputString
3 {
4     get { return this.inputString; }
5     set
6     {
7         if (value != inputString)
8         {
9             this.inputString = value;
10            OnPropertyChanged("InputString");
11        }
12    }
13 }
```

In the get method we simply return the value of the input data. The set method checks if the input value has changed, and, if so, sets the new input data and announces the change to the CrypTool 2 environment by calling the function *OnPropertyChanged(<Property name>)*. This step is necessary for input properties to update the quickwatch view.

The output data property (which handles the input data after it has been encrypted or decrypted) will in our example look as follows:

```

1 [PropertyInfo(Direction.OutputData, "Text output", "The string after
   processing with the Caesar cipher", "", false, false, DisplayLevel.
   Beginner, QuickWatchFormat.Text, null)]
2 public string OutputString
3 {
4     get { return this.outputString; }
5     set
6     {
7         outputString = value;
8         OnPropertyChanged("OutputString");
9     }
10 }

```

CrypTool 2 does not require implementing set methods for output properties, as they will never be called from outside the plugin. Nevertheless, in our example the plugin itself accesses the property, and therefore we have chosen to implement the set method.

You can provide additional output data types if you so desire. In our example, we will also offer output data of type *CryptoolStream*, input data for external alphabets, and input data for the shift value of our Caesar algorithm. Note that for the first of these, the set method is not implemented since it will never be called. We shall define these properties as follows:

```

1 [PropertyInfo(Direction.OutputData, "CryptoolStream output", "The raw
   CryptoolStream data after processing with the Caesar cipher", "",
   false, false, DisplayLevel.Beginner, QuickWatchFormat.Text, null)]
2 public CryptoolStream OutputData
3 {
4     get
5     {
6         if (outputString != null)
7         {
8             CryptoolStream cs = new CryptoolStream();
9             listCryptoolStreamsOut.Add(cs);
10            cs.OpenRead(Encoding.Default.GetBytes(outputString.ToCharArray())
11            ));
12            return cs;
13        }
14        else
15        {
16            return null;
17        }
18    }
19    set { }
20 }
21 [PropertyInfo(Direction.InputData, "External alphabet input", "Input a
   string containing the alphabet to be used by Caesar.\nIf no
   alphabet is provided for this input, the internal default alphabet
   will be used.", "", false, false, DisplayLevel.Expert,

```

```

        QuickWatchFormat.Text, null)]
22 public string InputAlphabet
23 {
24     get { return ((CaesarSettings)this.settings).AlphabetSymbols; }
25     set
26     {
27         if (value != null && value != settings.AlphabetSymbols)
28         {
29             ((CaesarSettings)this.settings).AlphabetSymbols = value;
30             OnPropertyChanged("InputAlphabet");
31         }
32     }
33 }
34
35 [PropertyInfo(Direction.InputData, "Shift value (integer)", "This is
    the same setting as the shift value in the Settings pane but as
    dynamic input.", "", false, false, DisplayLevel.Expert,
    QuickWatchFormat.Text, null)]
36 public int ShiftKey
37 {
38     get { return settings.ShiftKey; }
39     set
40     {
41         if (value != settings.ShiftKey)
42         {
43             settings.ShiftKey = value;
44         }
45     }
46 }

```

2.9.4 Sending messages to the CrypTool 2 core

The CrypTool 2 API provides two methods to send messages from the plugin to the CrypTool 2 core. *GuiLogMessage* is used to send messages to the CrypTool 2 status bar. This method is a nice mechanism to inform the user as to what your plugin is currently doing. *OnPropertyChanged* is used to inform the core application of changes to any plugin properties and data. This may not affect the user interface, but is important to keep the core apprised of the plugin's current state.

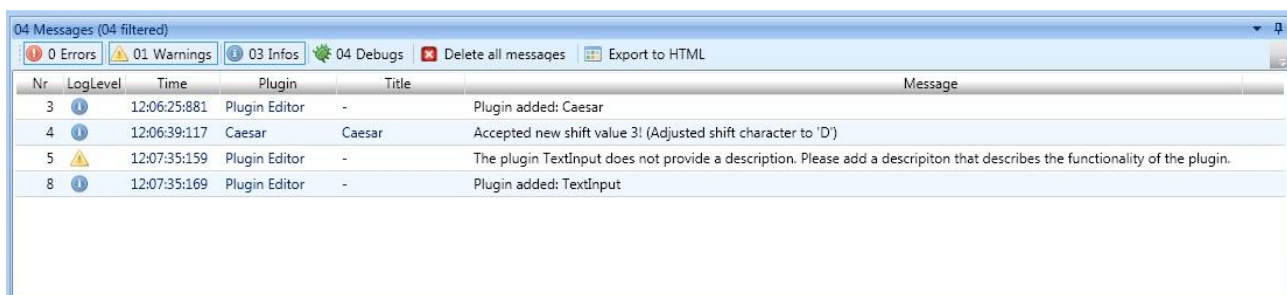

Figure 2.23: An example status bar.

The *GuiLogMessage* method takes two parameters:

- *Message* — the text to be shown in the status bar.
- *NotificationLevel* — the type of message, that is, its alert level:
 - `NotificationLevel.Error`
 - `NotificationLevel.Warning`
 - `NotificationLevel.Info`
 - `NotificationLevel.Debug`

Both of these notification methods also have associated events. Outlines of both related events will have been automatically generated by implementing the interface (see Section 2.5.4), but we must define the appropriate methods as follows:

```

1 public event GuiLogNotificationEventHandler
   OnGuiLogNotificationOccured;
2
3 private void GuiLogMessage(string message, NotificationLevel logLevel)
4 {
5     EventsHelper.GuiLogMessage(OnGuiLogNotificationOccured, this, new
        GuiLogEventArgs(message, this, logLevel));
6 }
7
8 public event PropertyChangedEventHandler PropertyChanged;
9
10 public void OnPropertyChanged(String name)
11 {
12     EventsHelper.PropertyChanged(PropertyChanged, this, new
        PropertyChangedEventArgs(name));
13 }

```

Note that to use *PropertyChangedEventHandler* you must include the namespace *System.ComponentModel*. Our collection of included namespaces should now look as follows:

```

1 using System;
2 using System.Collections.Generic;
3 using System.ComponentModel;
4 using System.Text;
5
6 using Cryptool.PluginBase;
7 using Cryptool.PluginBase.Cryptography;
8 using Cryptool.PluginBase.IO;
9 using Cryptool.PluginBase.Miscellaneous;

```

2.10 Completing the algorithmic code of the Caesar class

At this point, the plugin should be ready to be read by and shown correctly in the CrypTool 2 application. However, we haven't actually implemented the algorithm yet; we have just implemented interfaces and constructed a thorough set of properties. Algorithmic processing should be done in the *Execute()* function, as this is what CrypTool 2 will always call first. The actual functionality of your algorithm, as well as the structure thereof, is up to you. Note that an outline of the *Execute()* function will have been automatically generated by implementing the interface (see Section 2.5.4).

We have chosen to split our algorithm's encryption and decryption processes into two separate functions, which will both ultimately call the *ProcessCaesar()* function. Below is our implementation of the Caesar algorithmic processing and the *Execute()* function:

```

1 private void ProcessCaesar(CaesarMode mode)
2 {
3     CaesarSettings cfg = (CaesarSettings)this.settings;
4     StringBuilder output = new StringBuilder("");
5     string alphabet = cfg.AlphabetSymbols;
6
7     // If we are working in case-insensitive mode, we will use only
8     // capital letters, hence we must transform the whole alphabet
9     // to uppercase.
10    if (!cfg.CaseSensitiveAlphabet)
11    {
12        alphabet = cfg.AlphabetSymbols.ToUpper();
13    }
14
15    if (inputString != null)
16    {
17        for (int i = 0; i < inputString.Length; i++)
18        {
19            // Get the plaintext char currently being processed.
20            char currentchar = inputString[i];
21
22            // Store whether it is upper case (otherwise lowercase is
23            // assumed).
24            bool uppercase = char.IsUpper(currentchar);
25
26            // Get the position of the plaintext character in the alphabet.
27            int ppos = 0;
28            if (cfg.CaseSensitiveAlphabet)
29            {
30                ppos = alphabet.IndexOf(currentchar);
31            }
32            else
33            {
34                ppos = alphabet.IndexOf(char.ToUpper(currentchar));
35            }
36
37            if (ppos >= 0)
38            {
39                // We found the plaintext character in the alphabet,

```

```

39     // hence we will commence shifting.
40     int cpos = 0;
41     switch (mode)
42     {
43         case CaesarMode.encrypt:
44             cpos = (ppos + cfg.ShiftKey) % alphabet.Length;
45             break;
46         case CaesarMode.decrypt:
47             cpos = (ppos - cfg.ShiftKey + alphabet.Length) % alphabet.
48                 Length;
49             break;
50     }
51     // We have the position of the ciphertext character,
52     // hence just output it in the correct case.
53     if (cfg.CaseSensitiveAlphabet)
54     {
55         output.Append(alphabet[cpos]);
56     }
57     else
58     {
59         if (uppercase)
60         {
61             output.Append(char.ToUpper(alphabet[cpos]));
62         }
63         else
64         {
65             output.Append(char.ToLower(alphabet[cpos]));
66         }
67     }
68 }
69 else
70 {
71     // The plaintext character was not found in the alphabet,
72     // hence proceed with handling unknown characters.
73     switch ((CaesarSettings.UnknownSymbolHandlingMode)cfg.
74         UnknownSymbolHandling)
75     {
76         case CaesarSettings.UnknownSymbolHandlingMode.Ignore:
77             output.Append(inputString[i]);
78             break;
79         case CaesarSettings.UnknownSymbolHandlingMode.Replace:
80             output.Append('?');
81             break;
82     }
83 }
84 // Show the progress.
85 if (OnPluginProgressChanged != null)
86 {

```

```

87         OnPluginProgressChanged(this, new PluginProgressEventArgs(i,
88             inputString.Length - 1));
89     }
90     }
91     outputString = output.ToString();
92     OnPropertyChanged("OutputString");
93     OnPropertyChanged("OutputData");
94 }
95
96 public void Encrypt()
97 {
98     ProcessCaesar(CaesarMode.encrypt);
99 }
100
101 public void Decrypt()
102 {
103     ProcessCaesar(CaesarMode.decrypt);
104 }
105
106 public void Execute()
107 {
108     switch (settings.Action)
109     {
110         case 0:
111             GuiLogMessage("Encrypting", NotificationLevel.Debug);
112             Encrypt();
113             break;
114         case 1:
115             GuiLogMessage("Decrypting", NotificationLevel.Debug);
116             Decrypt();
117             break;
118         default:
119             break;
120     }
121 }

```

It is important to make sure that all changes to the output properties will be announced to the CrypTool 2 environment. In our example this happens by calling the set method of *OutputData*, which in turn calls *OnPropertyChanged* to indicate that both output properties *OutputData* and *OutputDataStream* have changed. Instead of calling the property's set method you could instead call *OnPropertyChanged* directly within the *Execute()* method.

You may have noticed that the *ProgressChanged* method is undefined. This method can be used to show the current algorithm process as a progress bar in the plugin icon. To use this method and compile successfully, you must declare this method, which we have done for our example below. Note that the *OnPluginProgressChanged* event will have been automatically generated by implementing the interface (see Section 2.5.4).

```

1 public event PluginProgressChangedEventHandler OnPluginProgressChanged
    ;
2
3 private void ProgressChanged(double value, double max)
4 {
5     EventsHelper.ProgressChanged(OnPluginProgressChanged, this, new
        PluginProgressEventArgs(value, max));
6 }

```

2.11 Performing a clean dispose

Be sure you have closed and cleaned all your streams after execution before CrypTool 2 decides to dispose the plugin instance. Though not required, we will run the disposal code before execution as well. We will expand the associated automatically generated methods (see Section 2.5.4) as follows:

```

1 public void Dispose()
2 {
3     foreach(CryptoolStream stream in listCryptoolStreamsOut)
4     {
5         stream.Close();
6     }
7     listCryptoolStreamsOut.Clear();
8 }
9
10 public void PostExecution()
11 {
12     Dispose();
13 }
14
15 public void PreExecution()
16 {
17     Dispose();
18 }

```

2.12 Finishing the implementation

When adding plugin instances to the CrypTool 2 workspace, the application core checks whether the plugin runs without any exceptions. If any method inherited from `IPlugin` throws an exception, CrypTool 2 will display an error message and prohibit use of the plugin. Therefore, we must remove the *NotImplementedException* from the automatically generated methods *Initialize()*, *Pause()* and *Stop()*. In our example it will be sufficient to provide empty implementations:

```

1 public void Initialize()
2 {
3 }
4
5 public void Pause()
6 {
7 }
8
9 public void Stop()
10 {
11 }

```

The methods *Presentation()* and *QuickWatchPresentation()* can be used to provide a specialized visualization of the plugin algorithm to be shown in CrypTool 2. Take a look at the *PRESENT* plugin to see how a custom visualization can be realized. For our Caesar example, we have chosen not to implement a custom visualization. Therefore we will simply return `null`:

```

1 public UserControl Presentation
2 {
3     get { return null; }
4 }
5
6 public UserControl QuickWatchPresentation
7 {
8     get { return null; }
9 }

```

Your plugin should compile without errors at this point.

2.13 Importing and testing the plugin

After you have built the plugin, you need to move the newly created plugin DLL to a location where CrypTool 2 can find it. There are currently a couple different ways to accomplish this. First, though, you need to locate the DLL. Once you have successfully compiled the plugin, the DLL should be in `|CrypPluginBase|bin|Debug`.

2.13.1 Custom storage

The first possibility is to copy your plugin's DLL file to the *CrypPlugins* folder located in the *Application Data* folder in your home folder. In Windows XP, the home folder path should be as follows: `C:\Documents and Settings\<user name>\Application Data\CrypPlugins`, and in Vista and Windows 7 the path should look like: `C:\Users\<user name>\Application Data\CrypPlugins`. This home folder path is called “custom storage” in the CrypTool architecture. Changes in this folder will only take effect for current user. After copying the file, you must restart CrypTool 2.

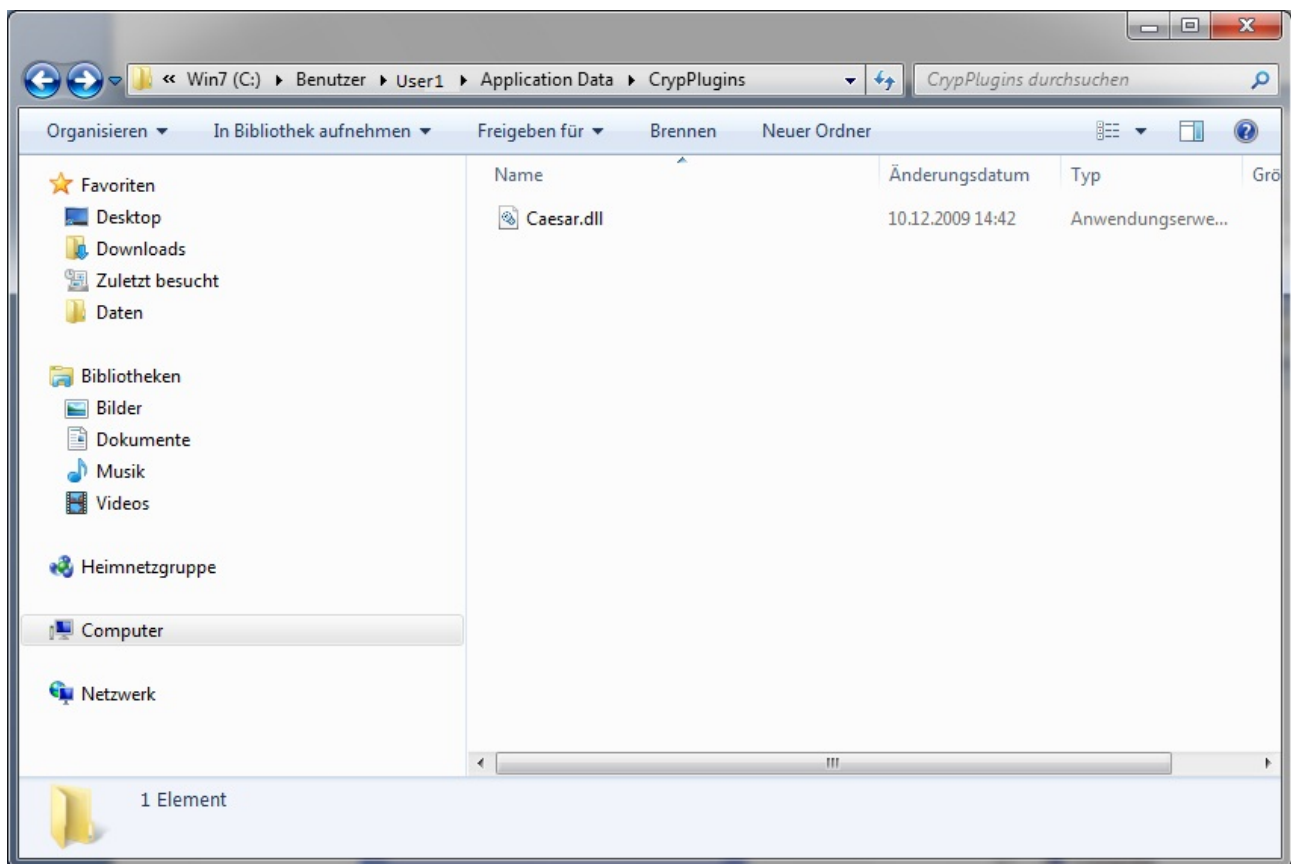

Figure 2.24: The custom storage folder.

2.13.2 Using build settings

Alternatively, you can use the build settings in your plugin's project properties to copy the DLL automatically after building it in Visual Studio. To set this up, right-click on your plugin project and select *Properties*:

Figure 2.25: Selecting the solution properties.

Then select *Build Events*:

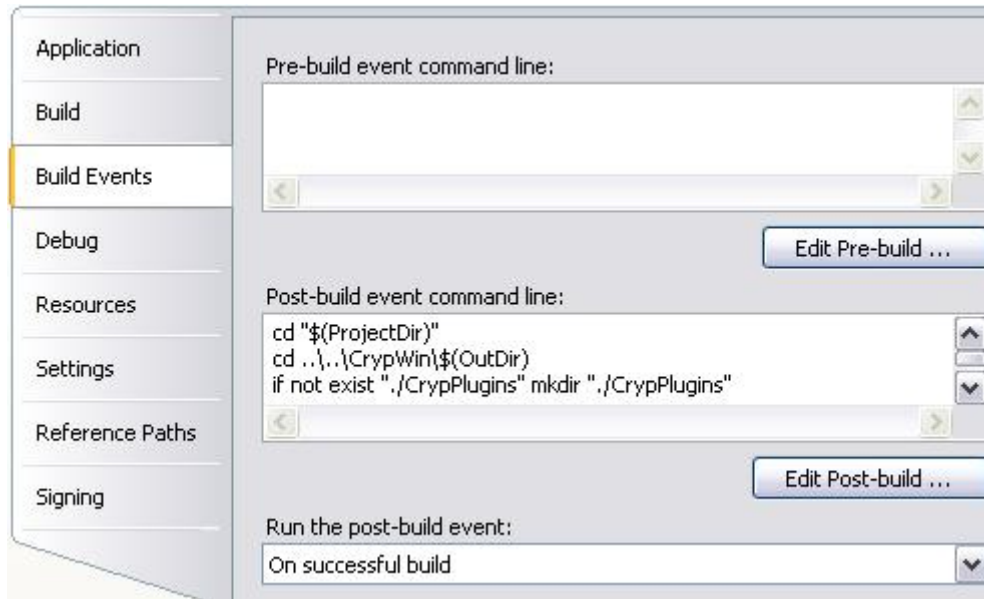

Figure 2.26: Setting the build events.

And finally, enter the following text into the *Post-build event command line* field:

```
cd "$(ProjectDir)"
cd ../../CrypWin\bin\Debug
if not exist ".\CrypPlugins" mkdir ".\CrypPlugins"
del /F /S /Q /s /q "Caesar*.*"
copy "$(TargetDir)Caesar*.*" ".\CrypPlugins"
```

You will need to change the highlighted fields to your particular plugin's name.

2.14 Drawing the workflow of your plugin

Each plugin should have an associated workflow file to show the algorithm in action in CrypTool 2. These workflow files are saved with the special *.cte* file extension. You can view the example files from other plugins by opening any of the files in the *\ProjectSamples* folder with CrypTool 2. Below is a sample workflow for our Caesar example:

Figure 2.27: A sample workflow diagram for the Caesar algorithm.

As your last step of development, once your plugin runs smoothly, you should also create one of these sample workflow files for your plugin. Such a file can be automatically created by simply saving a CrypTool 2 workspace project featuring your plugin. You should store the workflow file in the *\ProjectSamples* folder and make sure to commit the file to the SVN repository (see Section 1.2.3).
