

CrypTool 2.0

Plugin Developer Manual

- How to build your own plugins for CrypTool 2.0 -

S. Przybylski, A. Wacker, M. Wander, F. Enkler and P. Vacek $\{przybylski|wacker|wander|enkler|vacek\}@cryptool.org$

Version: 0.5 April 15, 2010 CrypTool 2 is the modern successor of the well-known e-learning platform for cryptography and cryptanalysis CrypTool 1, which is used worldwide for educational purposes at schools and universities as well as in companies and agencies.

Since the first launch of CrypTool 1 in 1999 the art of software development has changed dramatically. The CrypTool 2 team began working in 2008 to develop a completely new e-learning application, embracing the newest trends in both didactics and software architecture to delight the end-user with an entirely new experience.

To reach these goals, CrypTool 2 is built using the following:

- .NET (a modern software framework from Microsoft with solutions to common programming problems)
- C# (a modern object-oriented programming language, comparable to Java)
- WPF (a modern purely vector-based graphical subsystem for rendering user interfaces in Windows-based applications)
- Visual Studio 2008 (a development environment)
- Subversion (a source code and documentation version management system)

This document is intended for plugin developers who want to contribute new visual or mathematical functionality to CrypTool 2. As of January 2010, the program consists of over 7000 lines of C# code in the core application and over 250,000 lines of C# code in about 100 plugins.

For further information, please visit the CrypTool 2 website at http://www.cryptool2.vs.uni-due.de.

1 Developer Guidelines

CrypTool 2.0 is built upon state-of-the-art technologies such as .NET 3.5 and the Windows Presentation Foundation. Before you can start writing code and adding to the development of the project, a few things need to be considered. To make this process easier, please read through this document and follow the instructions closely. This document exists to help get you started by showing you how CrypTool 2 plugins are built in order to successfully interact with the application core. We have tried to be very thorough, but if you encouter a problem or error that is not described here, please let us know. Not only do we want to help get you up and running, but we also want to add the appropriate information to this guide for the benefit of other future developers.

In this first chapter we will describe all steps necessary in order to compile CrypTool 2 on your own computer. This is always the first thing you need to do before you can begin developing your own plugins and extensions. The basic steps are:

- Getting all prerequisites and installing them
- Accessing and downloading the source code with SVN
- Compiling the latest version of the source code

1.1 Prerequisites

Since CrypTool 2 is based on Microsoft .NET 3.5, you will need a Microsoft Windows environment. (Currently no plans exist for porting this project to Mono or other platforms.) We have successfully tested with Windows XP. Windows Vista and Windows 7.

Since you are reading the developer guidelines, you probably want to develop something. Hence, you will need a development environment. In order to compile our sources you need **Microsoft Visual Studio 2008 Professional**. Make sure to always install the latest service packs for Visual Studio. Unfortunately, our sources do not work smoothly with the freely available Visual C# Express. This is due to the fact that a major part of the application core, CrypWin, uses a commercial component and is therefore distributed only as a binary. The current version of Visual C# Express does not accept a binary file as a start-up project, and thus debugging is quite cumbersome. We hope to resolve this issue later in 2010 when the project is ported to Visual Studio 2010, but until then, we recommend using the full Visual Studio 2008 Professional version.

In order to run or compile our source code you will need at least the Microsoft .NET 3.5 framework with Service Pack 1 (SP1). Usually the installation of Visual Studio also installs the .NET framework, but if you do not have the latest version, you can get it for free from Microsoft's website. Once the framework has been installed, your development environment should be ready for our source code.

1.2 Accessing the Subversion (SVN) repository

Next you will need a way of accessing and downloading the source code. For the CrypTool 2 project we use **Subversion (SVN)** for version control, and hence you will need an SVN client, i.e. **TortoiseSVN** or the **svn commandline from cygwin**, to access our repository. It does not matter which client you use, but if SVN is new to you, we suggest using TortoiseSVN, since it offers a handy, straightforward Windows Explorer integration. We will guide you through how to use TortoiseSVN, although you should be able to use any SVN client in a similar fashion.

1.2.1 Checking out the sources

First, download and install TortoiseSVN. This will require you to reboot your computer, but once it is back up and running, create a directory (for instance, CrypTool2) somewhere on your computer for storing the local working files. Right-click on this directory; now that TortoiseSVN has been installed, you should see a few new items in the context menu. Select SVN Checkout:

Figure 1.1: Selecting SVN Checkout from the context menu after installing TortoiseSVN.

A window will now appear that will ask you for the URL of the repository that you would like to access. Our code repository is stored at https://www.cryptool.org/svn/CrypTool2/, and this is what you should enter in the appropriate field. The *Checkout directory* should already be filled in correctly with your new folder, and you shouldn't need to change any other options.

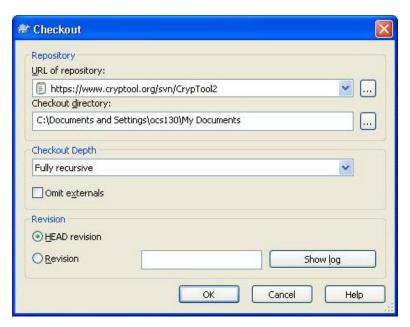

Figure 1.2: Checking out the CrypTool 2 repository.

Then just hit OK. You may be asked to accept a certificate (which you should accept), and you will certainly be asked for login information. If you are a registered developer, you should have already been given a username and password, and you should enter them here. (These are the same username and password that you can use for the CrypTool 2 development wiki.) If you are a guest and just want to download the source code, you can use "anonymous" as the username and an empty password. Mark the checkbox for saving your credentials if you don't want to enter them every time you work with the repository. Finally, hit OK, and the whole CrypTool 2 repository will begin downloading into your chosen local directory.

Since CrypTool 2 is a collaborative project with many developers, changes are made to the repository rather frequently. You should maintain a current working copy of the files to ensure your interoperability with the rest of the project, and thus you should update to the latest version as often as possible. You can do this by right-clicking on any directory within the working files and choosing SVN Update from the context menu.

A TortoiseSVN tutorial can be found at http://www.mind.ilstu.edu/research/robots/iris4/developers/syntutorial.

1.2.2 Adjusting the SVN settings

If you are a registered developer, you can commit your file changes to the public CrypTool 2 repository. However, before you do, you should edit your settings to make sure that you only check in proper source code. First, bring up the TortoiseSVN settings window:

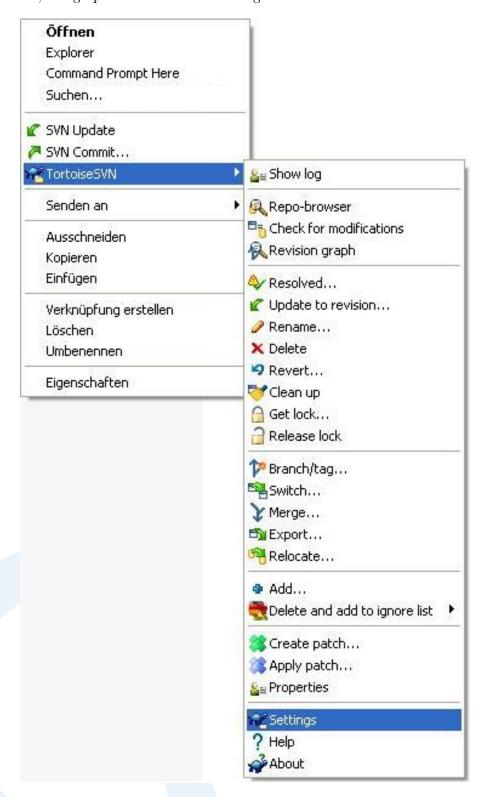

Figure 1.3: Getting to the TortoiseSVN settings.

The settings window will look something like this:

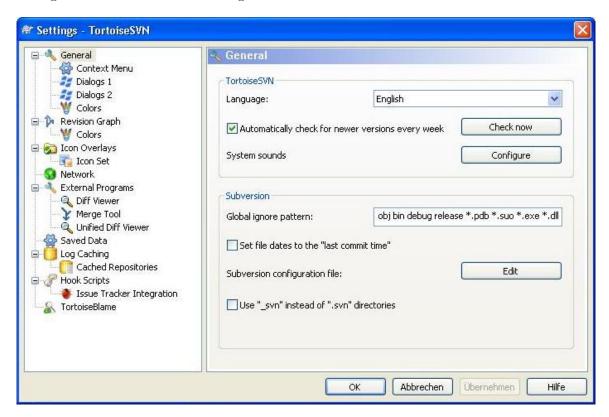

Figure 1.4: The TortoiseSVN settings window with the proper ignore pattern.

Then in the Global ignore pattern field, please enter the following text:

```
obj bin debug release *.pdb *.suo *.exe *.dll *.aux *.dvi *.log *.bak *.bbl *.blg *.user
```

You are free to also leave in any default pattern text or to write your own additions; this pattern serves simply to tell TortoiseSVN what kinds of files to ignore. You can now click OK to save your settings and close the window.

1.2.3 Committing your changes

Once you start writing code and developing your plugin, you should check your work into the project repository. If you are reading this document in sequence, you are probably not ready to do this, but while we are on the topic of SVN we will describe the process. To upload your changes, right-click on a directory within the working files that contains your changes and select SVN Commit from the context menu:

Figure 1.5: Selecting SVN Commit from the context menu.

When you commit your code, you can leave a comment to describe what you have changed. Please always provide meaningful descriptions of your updates. You can also select exactly which files you want to check in. The ignore pattern that we recommended should prevent most undesirable files from being in the list, but double-check to make sure everything you want to upload is included but nothing more. In general, you should never check in compiled and automatically generated files. For example, do not check in the entire $bin \mid$ and $obj \mid$ directories that Visual Studio generates. The server will reject your commits if you try to do so. You should commit your sources to our SVN repository as often as you can, but only commit code that successfully compiles and runs!

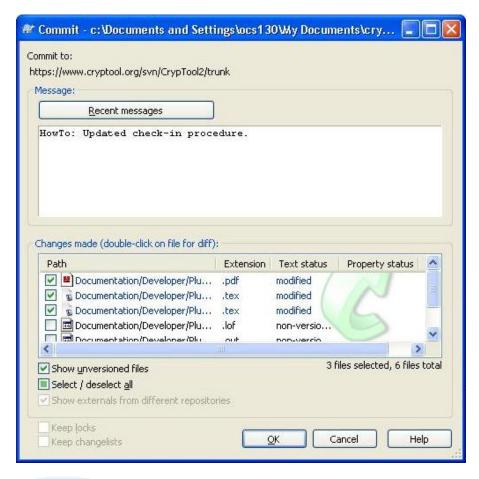

Figure 1.6: Providing comments for a commit.

You can use the SVN comments to link to your changes to a particular issue or bug ticket on the CrypTool 2 development wiki. (The list of active tickets can be found here.) The following commands are supported (note that there are multiple variations of each command that are functionally identical):

closes, fixes: The specified ticket will be closed and the contents of this commit message will be added to its notes. references, refs, addresses, re: The contents of this commit message will be added to the specified ticket's notes, but the status will be left unaltered.

You can apply the commands to multiple tickets simultaneously. The command syntax is as follows (again note that there are multiple variations that are functionally identical):

```
command #1
command #1, #2
command #1 & #2
command #1 and #2
```

You can also use more than one command in a message if necessary. For example, if you want to close tickets #10 and #12, and add a note to #17, you could type the following:

```
Changed blah and foo to do this or that. Fixes #10 and #12, and refs #17.
```

The comments can also be used to override the ignore pattern that the server is designed to block. However, please do not do this unless you are absolutely sure that you know what you are doing. If you are, you must use the *override-bad-extension* command and provide an explicit list of the file and directory names that you want to upload that need to override the ignore pattern. For example, if you want to check in a library file named someLib.dll, you must write something like the following:

```
This library is required by all developers, so I am adding it explicitly to the repository.

override-bad-extension: someLib.dll
```

Note that any text after the colon and the whitespace will be treated as the file name. Therefore, do not use quotation marks and do not write any text after the file name.

1.3 Compiling the sources

By this point you should have checked out a copy of the entire CrypTool 2 repository. Compiling is pretty easy; just go to the trunk directory and open the $CrypTool\ 2.0.sln$ Visual Studio solution. The Visual Studio IDE should open with all the working plugin components nicely arranged. If you are now starting Visual Studio for the first time, you will have to choose your settings. Just select either $most\ common$ or C#— you can change this at any time later. On the right side is the project explorer, where you can see all the subprojects included in the solution. Look for the project CrypWin.exe there. Once you have found it, right-click on it and select $Set\ as\ StartUp\ Project$ from the context menu. Next, go to the menu bar and select $Build\ Dolution$.

You may have to wait a while for the program to compile. Once it is finished, select Debug o Start Debugging. CrypTool 2 should now start for the first time with your own compiled code. Presumably you have not changed anything yet, but you now have your own build of all the components (with the exception of CrypWin and AnotherEditor, since they are available only as binaries). If the program does not compile or start correctly, please consult our FAQ and let us know if you found a bug.

If you are a **core developer**, hence somebody who can also compile CrypWin and AnotherEditor, you should use the *CrypTool 2.0.sln* solution from the *trunk*\| *CoreDeveloper*\| directory (which will not be visible to you if you are not a core developer). As a core developer, be aware that when you compile, you **change the** *CrypWin.exe* that is visible to everybody else. Thus, when committing to the repository, please make sure you really want to check in a new binary. Core developers can also build a new setup and publish it as beta release on the website. This process is explained in the wiki at https://www.cryptool.org/trac/CrypTool2/wiki/BuildSetup.

2 Plugin Implementation

In this chapter we provide step-by-step instructions for implementing your own CrypTool 2 plugin. The given instructions refer primarily to the usage of **Microsoft Visual Studio Professional 2008**, so before starting you should have a copy of the program installed on your computer.

2.1 Downloading the example and template

We will use the **Caesar cipher** (also known as the **shift cipher**) as an example throughout this chapter. If you did not to download the entire CrypTool 2 source code as described in Section 1.2.1, you can still get a copy of the source code for the Caesar algorithm referenced throughout this guide from the following location:

username: anonymous
password: (not required)

https://www.cryptool.org/svn/CrypTool2/trunk/CrypPlugins/Caesar/

We have also created a Visual Studio plugin **template** to help with the development of new plugins. Using this template is strongly recommended over copying and pasting code from this document! The template can be found here:

http://cryptool2.vs.uni-due.de/downloads/template/encryptionplugin.zip

2.2 Creating a new project

To begin, open Visual Studio, go to the menu bar and select $File \rightarrow New \rightarrow Project...$ The following window will appear:

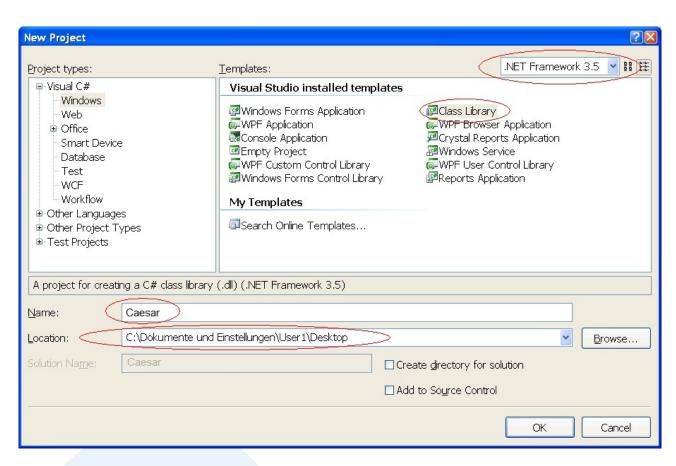

Figure 2.1: Creating a new Visual Studio project.

Select .NET-Framework 3.5 as the target framework. Then choose Class Library as the default template, as this will build the project for your plugin as a DLL file. Give the project a unique and meaningful name (such as Caesar in our case), and choose a location to save it to. Select the subdirectory CrypPlugins from your SVN trunk as the location. Finally, confirm by pressing the OK button. Note that creating a new project in this manner also creates a new solution into which the project is placed. At this point, your Visual Studio solution should look like this:

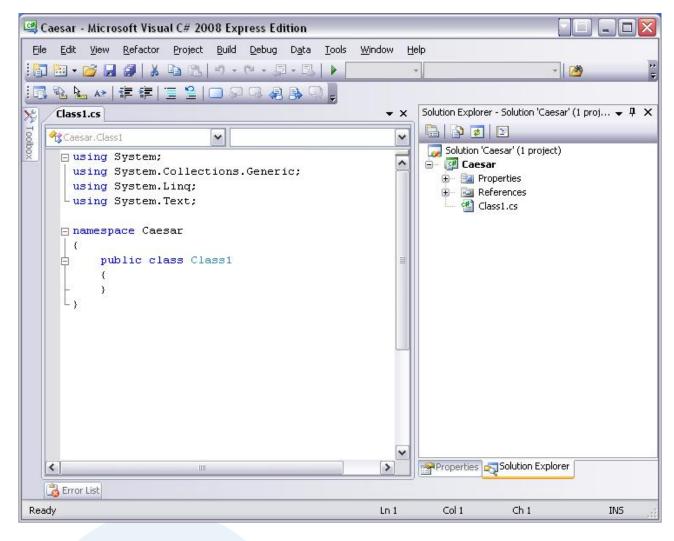

Figure 2.2: A newly created solution and project.

2.3 Interface selection

To include our new plugin in the CrypTool 2 application, we must first add a reference to the CrypTool 2 library *CrypPluginBase.dll*, where all the necessary CrypTool 2 plugin interfaces are declared.

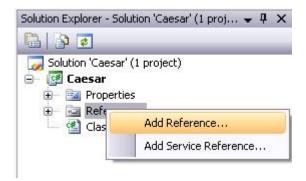

Figure 2.3: Adding a new reference.

Right-click in the Solution Explorer on the *Reference* item and choose *Add Reference*. A window like the following should appear:

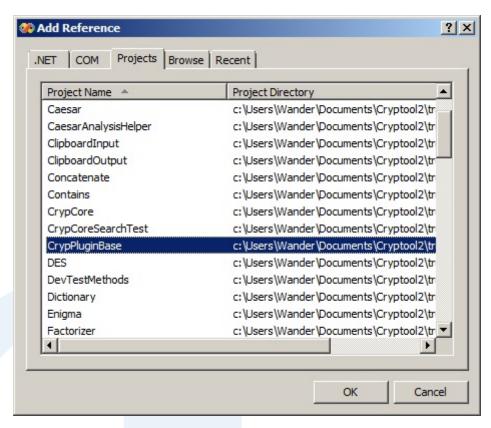

Figure 2.4: Adding a reference to the CrypPluginBase source code.

Unless you have created your new project in the same CrypTool 2 solution, you probably will not be able to select the library directly as seen above in Figure 2.4; instead you can browse for the binary DLL as seen below in Figure 2.5. Click on the *Browse* tab and navigate to the folder in which you downloaded the CrypTool 2 project. Within that folder, go to |CrypPluginBase|bin|Debug and select the file CrypPluginBase.dll. The library reference can then be added by double clicking the file or pressing the OK button.

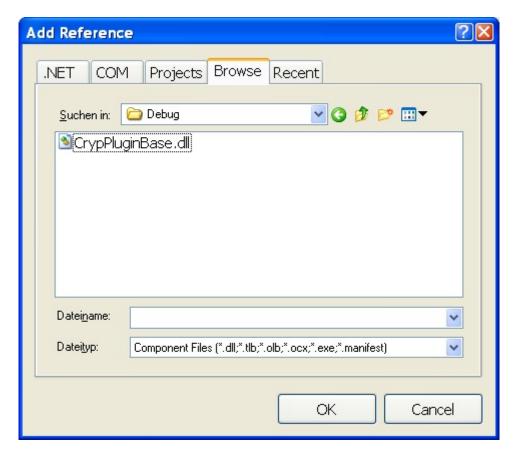

Figure 2.5: Browsing for a reference.

Besides CrypPluginBase you will need to add three Windows assembly references to provide the necessary namespaces for the user control functions Presentation and QuickWatchPresentation. This can be done in a similar manner as before with the CrypPluginBase reference, but by selecting the .NET tab and searching for the references there. Select the following .NET components:

- PresentationCore
- \bullet PresentationFramework
- WindowsBase

After these additions, your reference tree view should look like this:

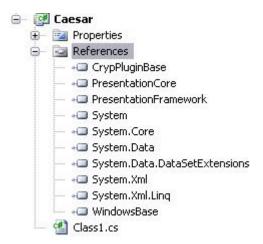

Figure 2.6: A reference tree with the essential components.

If your plugin will require other additional libraries, you can add them in the same way.

2.4 Modifing the project properties

It is important to make two small changes to your plugin's assembly data to make sure that it will be imported correctly into CrypTool 2. Go to the Solution Explorer and open AssemblyInfo.cs, which can be found in the Properties folder. Make the following two changes:

- Change the attribute Assembly Version to have the value "2.0.*", and
- Comment out the attribute Assembly File Version.

This section of your assembly file should now look something like this:

```
1 [assembly: AssemblyVersion("2.0.*")]
2 //[assembly: AssemblyFileVersion("1.0.0.0")]
```

2.5 Creating classes for the algorithm and its settings

In the next step we will create two classes. The first class will be the main driver; we will call ours Caesar since that is the name of the cipher that it will implement. In our case, this class has to inherit from IEncryption because it will be an encryption plugin. If it was instead a hash plugin, this class should inherit from IHash. The second class will be used to store setting information for the plugin, and thus we will name ours CaesarSettings. It will need to inherit from ISettings.

2.5.1 Creating a class for the algorithm

When starting a new project, Visual Studio automatically creates a class named *Class1.cs*. Since this is a rather non-descriptive name, we will change it. In our example, it will be *Caesar.cs*. There are two ways to change the name:

- Rename the existing class, or
- Delete the existing class and create a new one.

Both options will achieve the same results. We will guide you through the second method. First, delete Class 1.cs.

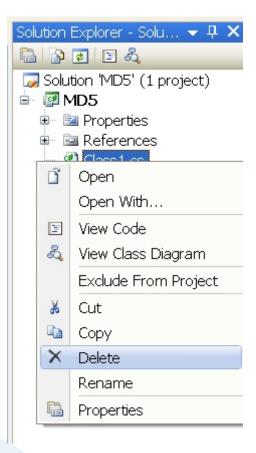

Figure 2.7: Deleting a class.

Then right-click on the project item (in our case, Caesar) and select $Add \rightarrow Class...$:

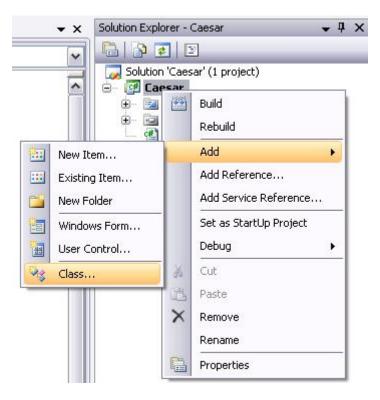

Figure 2.8: Adding a new class.

Finally, give your class a unique name. We will call our class *Caesar.cs* and define it as public so that it will be available to other classes.

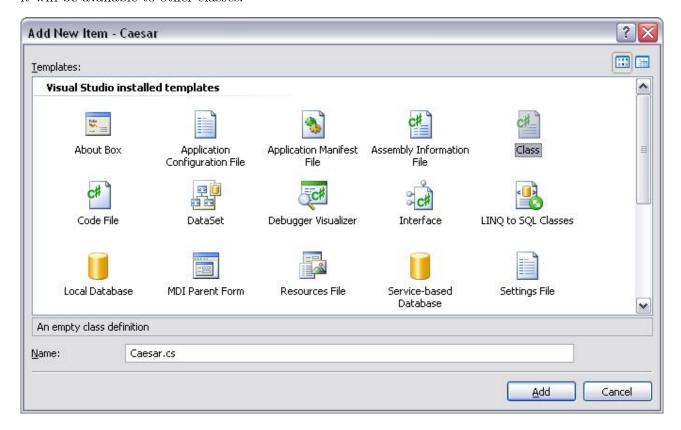

Figure 2.9: Naming the new class.

Note that Visual Studio will automatically generate a very basic code outline for the new class. In our example, we will not use the all the namespaces that are automatically imported, so you can delete the line using System.Linq;.

2.5.2 Creating a settings class

Add a second public class in the same way. We will call the class *CaesarSettings*. The settings class will store the necessary information about controls, captions, descriptions and default parameters (e.g. for key settings, alphabets, key length and type of action) to build the **TaskPane** in the CrypTool application.

Below is an example of what a completed TaskPane for the existing Caesar plugin in CrypTool 2 looks like:

Figure 2.10: The completed TaskPane for the existing Caesar plugin.

2.5.3 Adding the namespaces and inheritance sources for the Caesar class

Open the Caesar.cs file by double clicking on it in the Solution Explorer. To include the necessary namespaces in the class header, use the using statement followed by the name of the desired namespace. The CrypTool 2 API provides the following namespaces:

- Cryptool. PluginBase contains interfaces such as IPlugin, IHash, and ISettings, as well as attributes, enumerations, delegates and extensions.
- Cryptool. Plugin Base. Analysis contains interfaces for cryptanalysis plugins (such as Stream Comparator).
- Cryptool. Plugin Base. Control contains global interfaces for the IControl feature for defining custom controls.
- Cryptool. Plugin Base. Cryptography contains interfaces for encryption and hash algorithms such as AES, DES and MD5.
- Cryptool. Plugin Base. Editor contains interfaces for editors that can be implemented in CrypTool 2, such as the default editor.
- Cryptool. PluginBase. Generator contains interfaces for generators, including the random input generator.
- Cryptool. Plugin Base. IO contains interfaces for input, output and the Cryptool Stream.
- Cryptool. PluginBase. Miscellaneous contains assorted helper classes, including GuiLog Message and Property Changed.
- Cryptool. PluginBase. Resources used only by CrypWin and the editor; not necessary for plugin development.
- Cryptool. Plugin Base. Tool contains an interface for all external tools implemented by CrypTool 2 that do not entirely support the CrypTool 2 API.
- Cryptool. Plugin Base. Validation contains interfaces for validation methods, including regular expressions.

In our example, the Caesar algorithm necessitates the inclusion of the following namespaces:

- Cryptool. PluginBase to implement ISettings in the Caesar Settings class.
- Cryptool. PluginBase. Cryptography to implement IEncryption in the Caesar class.
- Cryptool.PluginBase.IO to use CryptoolStream for data input and output.
- Cryptool. PluginBase. Miscellaneous to use the CrypTool event handler.

It is important to define a new default namespace for our public class (Caesar). In CrypTool 2 the standard namespace convention is Cryptool.[name of class]. Therefore our namespace will be defined as Cryptool.Caesar.

At this point, the source code should look like the following:

```
1 using System;
2 using System.Collections.Generic;
 using System. Text;
5 //required CrypTool namespaces
6 using Cryptool.PluginBase;
vusing Cryptool.PluginBase.Cryptography;
8 using Cryptool.PluginBase.IO;
  using Cryptool.PluginBase.Miscellaneous;
  namespace Cryptool.Caesar
12
    public class Caesar
13
14
    }
15
16 }
```

Next we should let the Caesar class inherit from IEncryption by making the following alteration:

```
namespace Cryptool.Caesar

{
    public class Caesar : IEncryption
    {
      }
    }
}
```

2.5.4 Adding interface functions to the Caesar class

You may notice an underscore underneath the I in IEncryption. Move your mouse over it, or place the cursor on it and press Shift+Alt+F10 and the following submenu should appear:

```
namespace Cryptool.Caesar {

    public class Caesar : IEncryption |
    {

        Implement interface 'IEncryption'

    }
}

Explicitly implement interface 'IEncryption'
```

Figure 2.11: An inheritance submenu.

Select the item *Implement interface 'IEncryption*'. Visual Studio will automatically generate all the interface members necessary for interaction with the CrypTool 2 core. (This step will save you a lot of typing!)

Your code should now look like this:

```
1 using System;
2 using System.Collections.Generic;
 using System. Text;
5 using Cryptool.PluginBase;
6 using Cryptool.PluginBase.Cryptography;
vusing Cryptool.PluginBase.IO;
  using Cryptool.PluginBase.Miscellaneous;
10 namespace Cryptool.Caesar
  {
11
      public class Caesar : IEncryption
12
13
          #region IPlugin Members
14
          public void Dispose()
16
               throw new NotImplementedException();
1.8
19
          public void Execute()
21
               throw new NotImplementedException();
23
24
25
          public void Initialize()
26
               throw new NotImplementedException();
28
29
30
          public event GuiLogNotificationEventHandler
31
              OnGuiLogNotificationOccured;
32
          public event PluginProgressChangedEventHandler
33
              OnPluginProgressChanged;
34
          public event StatusChangedEventHandler OnPluginStatusChanged;
35
36
          public void Pause()
          {
38
               throw new NotImplementedException();
39
40
41
          public void PostExecution()
43
               throw new NotImplementedException();
44
4.5
46
          public void PreExecution()
```

```
{
48
               throw new NotImplementedException();
49
           }
50
           public System. Windows. Controls. UserControl Presentation
52
53
               get { throw new NotImplementedException(); }
54
           }
55
           public System. Windows. Controls. UserControl
              QuickWatchPresentation
           {
58
               get { throw new NotImplementedException(); }
59
           }
61
           public ISettings Settings
63
               get { throw new NotImplementedException(); }
64
           }
65
66
           public void Stop()
68
               throw new NotImplementedException();
69
70
71
           #endregion
73
           #region INotifyPropertyChanged Members
74
75
           public event System.ComponentModel.PropertyChangedEventHandler
76
               PropertyChanged;
77
           #endregion
78
      }
79
 }
80
```

2.5.5 Adding the namespace and interfaces to the CaesarSettings class

Let's now take a look at the second class in our example, CaesarSettings, by double-clicking on the CaesarSettings.cs file in the Solution Explorer. First, we need to again include the Cryptool.PluginBase namespace to the class header. Then we must let the settings class inherit from ISettings in the same manner as was done with the Caesar class. Visual Studio will again automatically generate code from the CrypTool interface as seen below. (In this case, we can remove the using System.Collections.Generic;, using System.Linq;, and using System.Text; lines, as we will not use those references.)

```
using System;
  using Cryptool.PluginBase;
3
  namespace Cryptool.Caesar
  {
6
      public class CaesarSettings : ISettings
8
           #region ISettings Members
9
10
           public bool HasChanges
11
12
               get
13
                {
14

2.5.6 Adding controls to the CaesarSettings class

The settings class is used to populate the TaskPane in the CrypTool 2 application so that the user can modify the plugin settings at will. Thus we will need to implement some controls, such as buttons and text boxes, to allow for the necessary interaction. If you will be implementing an algorithm that does not have any user-defined settings (i.e. a hash function), then this class can be left mostly empty; you will, however, still have to modify the HasChanges property to avoid a NotImplementedException. The following code demonstrates the modifications necessary to create the backend for the TaskPane for our Caesar algorithm. You can also look at the source code of other CrypTool 2 plugins for examples of how to create the TaskPane backend.

```
using System;
using System.ComponentModel;
using System.Windows;
using System.Windows.Controls;
```

```
6 using Cryptool.PluginBase;
8 namespace Cryptool.Caesar
9 {
      public class CaesarSettings : ISettings

2.6 Adding an icon to the Caesar class

Before we go back to the code of the Caesar class, we have to add an icon to our project, which will be shown in the CrypTool 2 ribbon bar and navigation pane. As there is currently no default, it is mandatory to add an icon. (It is planned to include a default icon in future versions.)

For testing purposes you can just create a simple black and white PNG image with any graphics editing program, such as MS Paint or Paint.NET. The proper image size is 40x40 pixels, but since the image will be rescaled if necessary, any size is technically acceptable.

Once you have saved your icon, you should add it directly to the project or to a subdirectory with it. In the project solution, we created a new folder named Images. This can be done by right-clicking on the project item (Caesar in our example) and selecting $Add \rightarrow New$ Folder. The icon can be added to this folder (or to the project directly, or to any other subdirectory) by right-clicking on the folder and selecting $Add \rightarrow Existing$ Item.

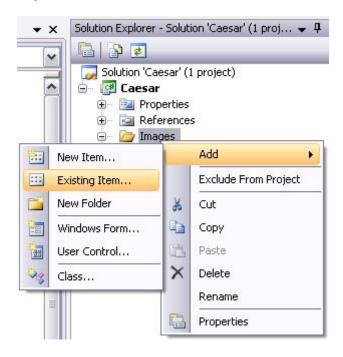

Figure 2.12: Adding an existing item.

A new window will then appear. Select *Image Files* as the file type and select your newly-created icon for your plugin.

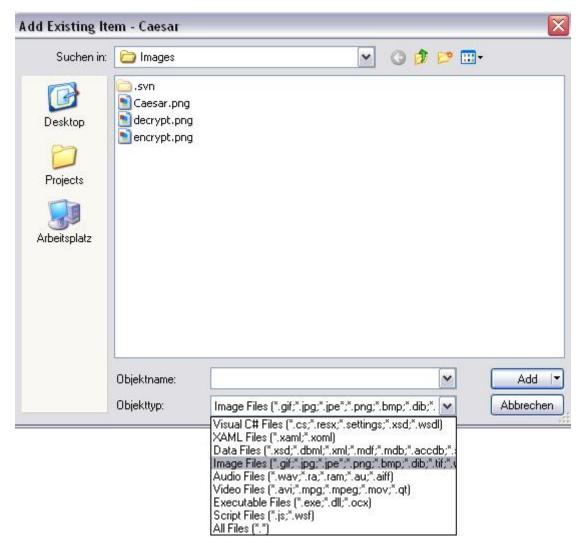

Figure 2.13: Selecting the image file.

Finally, we must set the icon as a *Resource* to avoid including the icon as a separate file. Right-click on the icon and select *Properties* as seen below.

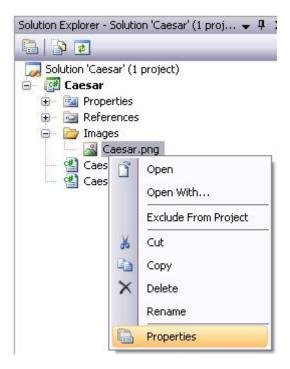

Figure 2.14: Selecting the image properties.

In the Properties panel, set the Build Action to Resource.

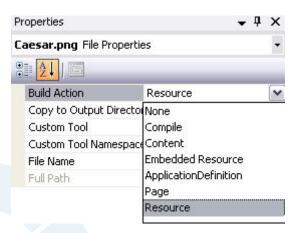

Figure 2.15: Selecting the icon's build action.

2.7 Defining the attributes of the Caesar class

Now let's go back to the code of the Caesar class (the *Caesar.cs* file in our example). The first thing we will do is define the attributes of our class. These attributes are used to provide additional information for the CrypTool 2 environment. If they are not properly defined, your plugin won't show up in the application user interface, even if everything else is implemented correctly.

Attributes are used for declarative programming and provide metadata that can be added to the existing .NET metadata. CrypTool 2 provides a set of custom attributes that are used to mark the different parts of your plugin.

These attributes can be defined anywhere within the *Cryptool.Caesar* namespace, but customarily they are defined right before the class declaration.

2.7.1 The [Author] attribute

The [Author] attribute is optional, meaning that we are not required to define it. The attribute can be used to provide additional information about the plugin developer (or developers, as the case may be). This information will appear in the TaskPane, as for example in Figure 2.10. We will define the attribute to demonstrate how it should look in case you want to use it in your plugin.

```
[Author ("Your Name", "youremail@abc.com", "Company ABC", "http://companyabc.com")]

▲ 1 of 2 ▼ AuthorAttribute.AuthorAttribute (string author, string email, string institute, string url)
Initializes a new instance of the AuthorAttribute class.
```

Figure 2.16: The defintion for the [Author] attribute.

As can be seen above, the author attribute takes four elements of type string. These elements are:

- Author the name of the plugin developer.
- Email the email address of the plugin developer, should he or she wish to be available for contact.
- Institute the organization, company or university with which the developer is affiliated.
- *URL* the website of the developer or of his or her institution.

All of these elements are optional; the developer can choose what information will be published. Unused elements should be set to null or an empty string.

2.7.2 The [PluginInfo] attribute

The second attribute, [PluginInfo], provides necessary information about the plugin, and is therefore mandatory. This information appears in the caption and tool tip window. The attribute is defined as follows:

Figure 2.17: The defintion for the [PluginInfo] attribute.

This attribute has the following parameters:

- Resource File the relative path of the associated resource file (if the plugin makes use of one). These files are used primarily to provide multilingual support for the plugin. This element is optional.
- Startable a flag that should be set to true only if the plugin is an input generator (i.e. if your plugin only has outputs and no inputs). In all other cases this should be set to false. This flag is important setting it incorrectly will result in unpredictable results. This element is mandatory.
- Caption the name of the plugin, or, if using a resource file, the name of the field in the file with the caption data. This element is mandatory.
- ToolTip a description of the plugin, or, if using a resource file, the name of the field in the resource file with the toolTip data. This element is optional.
- Description URL the local path of the description file (e.g. XAML file). This element is optional.
- *Icons* an array of strings to define all the paths of the icons used in the plugin (i.e. the plugin icon described in Section 2.5). This element is mandatory.

Unused elements should be set to null or an empty string.

(There are a few limitations and bugs that still exist in the [PluginInfo] attribute that will be resolved in a future version. Firstly, it is possible to use the plugin without setting a caption, although this is not recommended. In the future the plugin will fail to load without a caption. Secondly, a zero-length toolTip string currently causes the toolTip to appear as an empty box in the application. Lastly, the toolTip and description do not currently support internationalization and localization.)

In our example, the resource File parameter should be set to Cryptool. Caesar. Resource. res. This file will be used to store the label and caption text to support multilingualism.

The second parameter, *startable*, should be set to **false**, because our encryption algorithm is not an input generator.

The next two parameters are necessary to define the plugin's name and description. Since we are using a resource file, we should place here the names of the resource fields that contain the caption and toolTip. (We could also just write simple text strings instead of using outsourced references.)

The Description URL element defines the location path of the description file. The parameter is composed in the format <assembly name>/<file name> or, if you want to store your description files in a separate folder (as in our case), <assembly name>//<file name>. The description file

must be an XAML file. In our case, we shall create a folder named *DetailedDescription* in which to store our XAML file with any necessary images. Our folder structure now looks as follows:

Figure 2.18: The folder structure as seen in the Solution Explorer.

Once a detailed description has been written in the XAML file, it can be accessed in the CrypTool 2 application by right-clicking on the plugin icon in the workspace and selecting *Show description*.

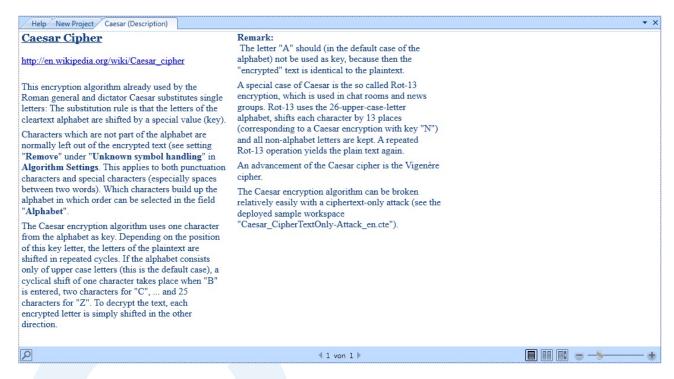

Figure 2.19: A detailed description provided through an XAML file.

The last parameter tells CrypTool 2 the names of the provided icons. This parameter is an array composed of strings in the format $< assembly\ name > / < file\ name >$ or $< assembly\ name > / < path > / < file\ name >$.

The first and most important icon is the plugin icon, which will be shown in CrypTool 2 in the ribbon bar and navigation pane. Once the icon has been added to the project as described in Section 2.5, we must accordingly tell CrypTool 2 where to find the icon. This can be seen above in Figure 2.17.

If your plugin will use additional icons, you should define the paths to each of them by adding the path strings to the [PluginInfo] attribute parameter list, each separated by a comma. We have added two further icons for the context menu in the CrypTool 2 workspace. (If you choose to add more icons, don't forget to add the icons to your solution.)

2.7.3 The [EncryptionType] attribute

The third and last attribute, [EncryptionType], is needed to tell CrypTool 2 what type of plugin we are creating. CrypTool 2 uses this information to place the plugin in the correct group in the navigation pane and ribbon bar. In our example, since Caesar is a classical algorithm, we will define the attribute as follows:

```
[EncryptionType (EncryptionType.Classic)]

▲1 of 2 ▼ EncryptionTypeAttribute.EncryptionTypeAttribute (EncryptionType encryptionType)
```

Figure 2.20: A defined [Encryption Type] attribute.

The possible values of the [Encryption Type] attribute are as follows:

- Asymmetric for asymmetrical encryption algorithms, such as RSA.
- Symmetric Block for block cipher algorithms, such as DES, AES and Twofish.
- SymmetricStream for stream cipher algorithms, such as RC4, Rabbit and SEAL.
- *Hybrid* for algorithms which are actually a combination of several algorithms, such as algorithms in which the data is encrypted symmetrically and the encryption key asymmetrically.
- Classic for classical encryption or hash algorithms, such as Caesar or MD5.

2.8 Defining the private variables of the settings in the Caesar class

The next step is to define some private variables that are needed for the settings, input, and output data. In our example, this will look like the following:

If your algorithm deals with long strings of code, it is recommended to use the *CryptoolStream* data type. This was designed for input and output between plugins and to handle large amounts of data. To use the native CrypTool stream type, include the namespace *Cryptool.PluginBase.IO* with a using statement as explained in Section 2.4.3.

Our example makes use of the following private variables:

- CaesarSettings settings required to implement the IPlugin interface properly.
- string inputString string from which to read the input data.
- string outputString string to which to save the output data.
- enum CaesarMode used to select either encryption or decryption.
- List<CryptoolStream> listCryptoolStreamsOut a list of all streams created by the plugin, which helps to perform a clean dispose.

2.9 Implementing the interfaces in the Caesar class

2.9.1 Connecting the settings class

The next major step is to write out our implementations of the interfaces. First we will add a constructor to our class. We will use this to create an instance of our settings class and a function to handle events:

```
public Caesar()

this.settings = new CaesarSettings();

this.settings.LogMessage += GuiLogMessage;
}
```

Secondly, we must implement the *Settings* property declared in the interface. An outline of this property should have been automatically generated by implementing the interface (see Section 2.4.4); just edit it appropriately to communicate with your settings class as we have done here:

```
public ISettings Settings

{
    get { return (ISettings)this.settings; }
    set { this.settings = (CaesarSettings)value; }
}
```

2.9.2 The input/output attributes

Next we will define five properties, each with an appropriate attribute, to be used for input and output. Th attributes are necessary to tell CrypTool 2 whether the properties are used for input or output and to provide the plugin with external data.

The attribute that we will use for each property is called [PropertyInfo] and it consists of the following elements:

- direction defines whether this property is an input or output property, e.g. whether it reads input data or writes output data. The possible values are:
 - Direction.Input
 - Direction.Output
- caption the caption for the property displayed over the input or output arrow of the icon after it has been placed in the editor; "Input stream" in the example below:

Figure 2.21: A possible property caption and toolTip.

- toolTip the toolTip for the property displayed over the input or output arrow of the icon after it has been placed in the editor; "Input data to be hashed" in the example above.
- descriptionUrl currently not used; fill it with null or an empty string.
- mandatory this flag determines whether an input must be attached by the user to use the plugin. If set to true, an input connection will be required or else the plugin will not be executed in the workflow chain. If set to false, connecting an input is optional. As this only applies to input properties, if the direction has been set to Direction.Output, this flag will be ignored.
- has Default Value if this flag is set to true, CrypTool 2 will assume that the property has a default input value that does not require user input.
- displayLevel determines in which display levels your property will be shown in CrypTool 2. These are used to hide more advanced item from less-experienced users; a beginner using the corresponding display level will not see the properties marked as any other level, but a professional using the appropriate display level will have access to everything. These levels are as follows:
 - DisplayLevel.Beginner
 - DisplayLevel.Experienced
 - DisplayLevel.Expert
 - DisplayLevel.Professional

- quick Watch Format determines how the content of the property will be shown in the quick-watch perspective. CrypTool 2 accepts the following quickwatch formats:
 - QuickWatchFormat.Base64
 - QuickWatchFormat.Hex
 - QuickWatchFormat.None
 - QuickWatchFormat.Text

Figure 2.22: A quickwatch display in hexadecimal.

• quick Watch Conversion Method — this is used to indicate a conversion method; most plugins do not ned to convert their data and thus should use a null value here. The quickwatch function uses the default system encoding to display data, so if your data is in another format, such as UTF-16 or Windows-1250, you should provide here the name of a conversion method as string. The header for such a method should look something like the following:

```
object YourMethodName(string PropertyNameToConvert)
```

2.9.3 Defining the input/output properties

The first of the five properties that we will define is *InputString*. This is used to provide our plugin with the data to be encrypted or decrypted:

```
1 [PropertyInfo(Direction.InputData, "Text input", "Input a string to
      processed by the Caesar cipher", "", true, false, DisplayLevel.
     Beginner, QuickWatchFormat.Text, null)]
2 public string InputString
 {
3
    get { return this.inputString; }
4
    set
5
6
      if (value != inputString)
      {
        this.inputString = value;
9
        OnPropertyChanged("InputString");
1.0
      }
11
    }
12
 }
13
```

In the get method we simply return the value of the input data. The set method checks if the input value has changed, and, if so, sets the new input data and announces the change to the CrypTool 2 environment by calling the function $OnPropertyChanged(<Property\ name>)$. This step is necessary for input properties to update the quickwatch view.

The output data property (which handles the input data after it has been encrypted or decrypted) will in our example look as follows:

```
1 [PropertyInfo(Direction.OutputData, "Text output", "The string after
     processing with the Caesar cipher", "", false, false, DisplayLevel.
     Beginner, QuickWatchFormat.Text, null)]
2 public string OutputString
 {
3
    get { return this.outputString; }
5
    set
    {
6
      outputString = value;
7
      OnPropertyChanged("OutputString");
8
    }
 }
10
```

CrypTool 2 does not require implementing set methods for output properties, as they will never be called from outside the plugin. Nevertheless, in our example the plugin itself accesses the property, and therefore we have chosen to implement the set method.

You can provide additional output data types if you so desire. In our example, we will also offer output data of type CryptoolStream, input data for external alphabets, and input data for the shift value of our Caesar algorithm. Note that for the first of these, the set method is not implemented since it will never be called. We shall define these properties as follows:

```
1 [PropertyInfo(Direction.OutputData, "CryptoolStream output", "The raw
     CryptoolStream data after processing with the Caesar cipher", "",
     false , false , DisplayLevel . Beginner , QuickWatchFormat . Text , null)]
2 public CryptoolStream OutputData
 {
3
    get
4
5
      if (outputString != null)
6
        CryptoolStream cs = new CryptoolStream();
8
        listCryptoolStreamsOut.Add(cs);
9
        cs.OpenRead(Encoding.Default.GetBytes(outputString.ToCharArray()
10
           ));
        return cs;
11
      }
12
      else
13
        return null;
15
16
17
    set { }
18
19
20
  [PropertyInfo(Direction.InputData, "External alphabet input", "Input a
      string containing the alphabet to be used by Caesar.\nIf no
     alphabet is provided for this input, the internal default alphabet
     will be used.", "", false, false, DisplayLevel.Expert,
```

```
QuickWatchFormat.Text, null)]
22 public string InputAlphabet
    get { return ((CaesarSettings)this.settings).AlphabetSymbols; }
24
    set
25
    {
26
      if
         (value != null && value != settings.AlphabetSymbols)
27
      {
28
        ((CaesarSettings)this.settings).AlphabetSymbols = value;
        OnPropertyChanged("InputAlphabet");
30
31
    }
32
  }
33
  [PropertyInfo(Direction.InputData, "Shift value (integer)", "This is
     the same setting as the shift value in the Settings pane but as
     dynamic input.", "", false, false, DisplayLevel.Expert,
     QuickWatchFormat.Text, null)]
36 public int ShiftKey
37
  {
    get { return settings.ShiftKey; }
38
    set
39
40
         (value != settings.ShiftKey)
      if
41
42
        settings.ShiftKey = value;
44
    }
45
 }
46
```

2.9.4 Sending messages to the CrypTool 2 core

The CrypTool 2 API provides two methods to send messages from the plugin to the CrypTool 2 core: GuiLogMessage (used to send messages to the CrypTool 2 status bar) and OnPropertyChanged (used to inform the core of changes to the plugin data). The GuiLogMessage method is a nice mechanism to inform the user as to what your plugin is currently doing.

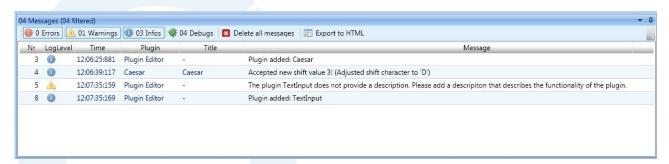

Figure 2.23: An example status bar.

The GuiLogMessage method takes two parameters:

- Message the text to be shown in the status bar.
- NotificationLevel the type of message, that is, its alert level:
 - NotificationLevel.Error
 - NotificationLevel.Warning
 - NotificationLevel.Info
 - NotificationLevel.Debug

Both of these notification methods also have associated events. Outlines of both related events will have been automatically generated by implementing the interface (see Section 2.4.4), but we must define the appropriate methods as follows:

Note that to use PropertyChangedEventHandler you must include the namespace System. ComponentModel. Our collection of included namespaces should now look as follows:

```
using System;
using System.Collections.Generic;
susing System.ComponentModel;
using System.Text;

cusing Cryptool.PluginBase;
using Cryptool.PluginBase.Cryptography;
using Cryptool.PluginBase.IO;
using Cryptool.PluginBase.IO;
using Cryptool.PluginBase.Miscellaneous;
```

2.10 Completing the algorithmic code of the Caesar class

At this point, the plugin should be ready to be read by and shown correctly in the CrypTool 2 application. However, we haven't actually implemented the algorithm yet; we have just implemented interfaces and constructed a thorough set of properties. Algorithmic processing should be done in the Execute() function, as this is what CrypTool 2 will always call first. The actual functionality of your algorithm, as well as the structure thereof, is up to you. Note that an outline of the Execute() function will have been automatically generated by implementing the interface (see Section 2.4.4).

We have chosen to split our algorithm's encryption and decryption processes into two separate functions, which will both ultimately call the ProcessCaesar() function. Below is our implementation of the Caesar algorithmic processing and the Execute() function:

```
private void ProcessCaesar(CaesarMode mode)
2 {
    CaesarSettings cfg = (CaesarSettings)this.settings;
3
    StringBuilder output = new StringBuilder("");
    string alphabet = cfg.AlphabetSymbols;
    // If we are working in case-insensitive mode, we will use only
    // capital letters, hence we must transform the whole alphabet
8
    // to uppercase.
9
    if (!cfg.CaseSensitiveAlphabet)
10
11
      alphabet = cfg.AlphabetSymbols.ToUpper();
12
    }
13
14
    if (inputString != null)
15
16
      for (int i = 0; i < inputString.Length; i++)</pre>
17
        // Get the plaintext char currently being processed.
19
        char currentchar = inputString[i];
20
21
        // Store whether it is upper case (otherwise lowercase is
22
           assumed).
        bool uppercase = char.IsUpper(currentchar);
23
        // Get the position of the plaintext character in the alphabet.
25
        int ppos = 0;
26
        if (cfg.CaseSensitiveAlphabet)
          ppos = alphabet.IndexOf(currentchar);
        }
30
        else
31
32
          ppos = alphabet.IndexOf(char.ToUpper(currentchar));
        }
35
        if (ppos >= 0)
36
37
          // We found the plaintext character in the alphabet,
38
```

```
// hence we will commence shifting.
39
           int cpos = 0;
40
           switch (mode)
41
             case CaesarMode.encrypt:
43
               cpos = (ppos + cfg.ShiftKey) % alphabet.Length;
44
               break;
45
             case CaesarMode.decrypt:
46
               cpos = (ppos - cfg.ShiftKey + alphabet.Length) % alphabet.
                  Length;
               break;
48
           }
49
50
           // We have the position of the ciphertext character,
           // hence just output it in the correct case.
52
           if (cfg.CaseSensitiveAlphabet)
           {
54
             output.Append(alphabet[cpos]);
55
           }
56
           else
57
             if (uppercase)
59
             {
60
               output.Append(char.ToUpper(alphabet[cpos]));
61
             }
62
             else
             {
               output.Append(char.ToLower(alphabet[cpos]));
65
66
           }
67
        }
68
        else
         {
           // The plaintext character was not found in the alphabet,
71
           // hence proceed with handling unknown characters.
72
           switch ((CaesarSettings.UnknownSymbolHandlingMode)cfg.
73
              UnknownSymbolHandling)
           {
             case CaesarSettings.UnknownSymbolHandlingMode.Ignore:
75
               output.Append(inputString[i]);
76
               break;
77
             case CaesarSettings.UnknownSymbolHandlingMode.Replace:
78
               output.Append('?');
79
               break;
           }
        }
82
83
         // Show the progress.
84
        if (OnPluginProgressChanged != null)
85
```

```
OnPluginProgressChanged(this, new PluginProgressEventArgs(i,
87
               inputString.Length - 1));
         }
88
       }
       outputString = output.ToString();
90
       OnPropertyChanged("OutputString");
91
       OnPropertyChanged("OutputData");
92
     }
93
  }
94
95
  public void Encrypt()
96
  {
97
     ProcessCaesar(CaesarMode.encrypt);
98
  }
99
100
  public void Decrypt()
101
102
     ProcessCaesar (CaesarMode.decrypt);
103
104
  }
105
  public void Execute()
106
107
     switch (settings.Action)
108
109
       case 0:
110
         GuiLogMessage("Encrypting", NotificationLevel.Debug);
111
         Encrypt();
112
         break;
113
       case 1:
114
         GuiLogMessage("Decrypting", NotificationLevel.Debug);
115
         Decrypt();
116
         break;
117
       default:
118
         break;
119
     }
120
  }
121
```

It is important to make sure that all changes to the output properties will be announced to the CrypTool 2 environment. In our example this happens by calling the set method of OutputData, which in turn calls OnPropertyChanged to indicate that both output properties OutputData and OutputDataStream have changed. Instead of calling the property's set method you could instead call OnPropertyChanged directly within the Execute() method.

You may have noticed that the *ProgressChanged* method is undefined. This method can be used to show the current algorithm process as a progress bar in the plugin icon. To use this method and compile successfully, you must declare this method, which we have done for our example below. Note that the *OnPluginProgressChanged* event will have been automatically generated by implementing the interface (see Section 2.4.4).

```
public event PluginProgressChangedEventHandler OnPluginProgressChanged
;

private void ProgressChanged(double value, double max)

EventsHelper.ProgressChanged(OnPluginProgressChanged, this, new PluginProgressEventArgs(value, max));
}
```

2.11 Performing a clean dispose

Be sure you have closed and cleaned all your streams after execution before CrypTool 2 decides to dispose the plugin instance. Though not required, we will run the disposal code before execution as well. We will expand the associated automatically generated methods (see Section 2.4.4) as follows:

```
public void Dispose()
2 {
    foreach(CryptoolStream stream in listCryptoolStreamsOut)
3
      stream.Close();
6
    listCryptoolStreamsOut.Clear();
  }
8
10 public void PostExecution()
11 {
    Dispose();
12
13 }
14
15 public void PreExecution()
16
    Dispose();
17
18
 }
```

2.12 Finishing the implementation

When adding plugin instances to the CrypTool 2 workspace, the application core checks whether the plugin runs without any exceptions. If any method inherited from IPlugin throws an exception, CrypTool 2 will display an error message and prohibit use of the plugin. Therefore, we must remove the NotImplementedException from the automatically generated methods Initialize(), Pause() and Stop(). In our example it will be sufficient to provide empty implementations:

```
public void Initialize()

public void Pause()

function of the state of the st
```

The methods Presentation() and QuickWatchPresentation() can be used to provide a specialized visualization of the plugin algorithm to be shown in CrypTool 2. Take a look at the PRESENT plugin to see how a custom visualization can be realized. For our Caesar example, we have chosen not to implement a custom visualization. Therefore we will simply return null:

```
public UserControl Presentation

{
    get { return null; }

}

public UserControl QuickWatchPresentation

{
    get { return null; }

}
```

Your plugin should compile without errors at this point.

2.13 Importing and testing the plugin

After you have built the plugin, you need to move the newly created plugin DLL to a location where CrypTool 2 can find it. There are a few different ways to accomplish this. First, though, you need to locate the DLL. Once you have successfully compiled the plugin, the DLL should be in |CrypPluginBase|bin|Debug.

2.13.1 Global storage

The first option is to copy your plugin's DLL file to the CrypPlugins folder in which the CrypTool 2 executable (CrypWin.exe) can be found.

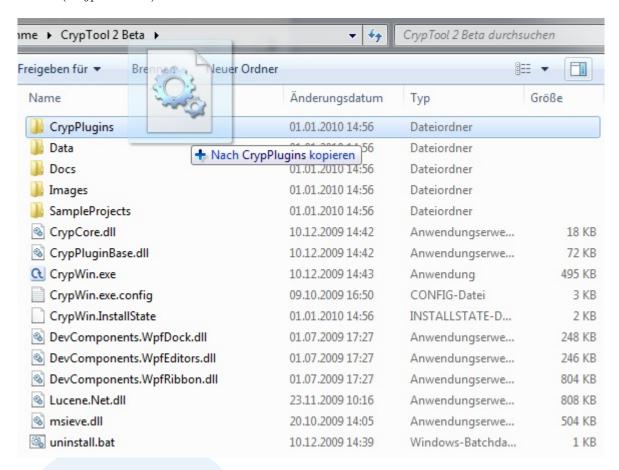

Figure 2.24: Copying the plugin to the global storage folder

This folder is known as "global storage" in the CrypTool 2 architecture. Changes in this folder will affect all users on a multi-user Windows platform. You should now restart CrypTool 2.

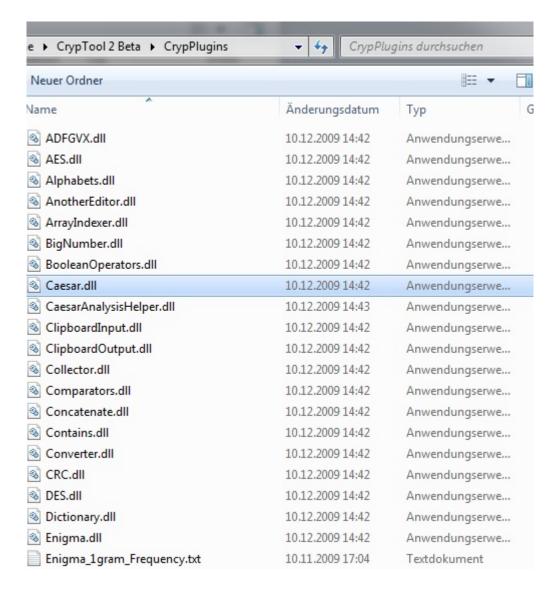

Figure 2.25: Inside the CrypPlugins folder (the global storage).

2.13.2 Custom storage

The second possibility is to copy your plugin's DLL file to the CrypPlugins folder located in the $Application\ Data$ folder in your home folder. In Windows XP, the home folder path should be as follows: $C:|Documents\ and\ Settings|< user\ name>|Application\ Data|CrypPlugins,$ and in Vista and Windows 7 the path should look like: $C:|Users|< user\ name>|Application\ Data|CrypPlugins.$ This home folder path is called "custom storage" in the CrypTool architecture. Changes in this folder will only take effect for current user. After copying the file, you must restart CrypTool 2.

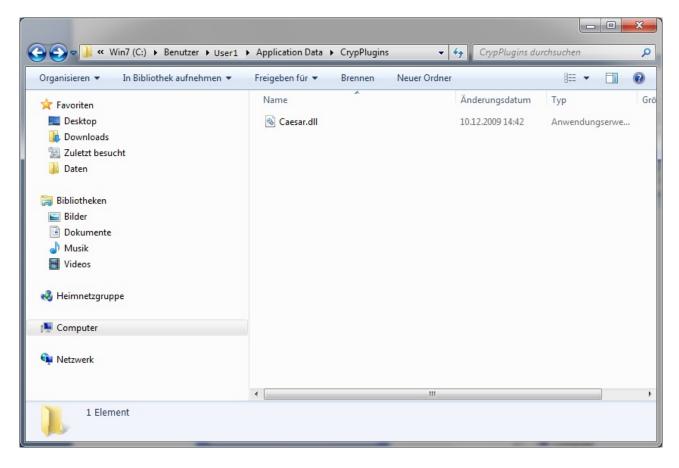

Figure 2.26: The custom storage folder.

2.13.3 Importing directly

Alternatively, you can import new plugins directly from the CrypTool 2 interface. Just run CrypWin.exe and select the *Download Plugins* button. An *Open File Dialog* window will open and ask where the new plugin is located. After selecting the new plugin, CrypTool 2 will automatically import the plugin to the custom storage folder. With this option you will not have to restart the program. All corresponding menu entries will be updated automatically. Note that this import function only accepts **signed** plugins, and also that this option is just a temporary solution: in the future this will be done online by a web service.

2.13.4 Using build settings

Yet another option is to use the build settings in your plugin's project properties to copy the DLL automatically after building it in Visual Studio. To set this up, right-click on your plugin project and select *Properties*:

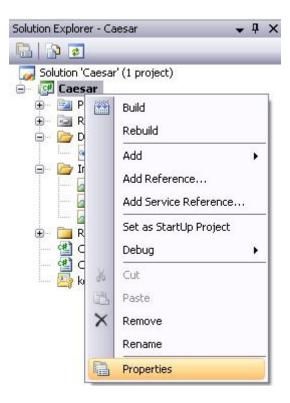

Figure 2.27: Selecting the solution properties.

Then select Build Events:

Figure 2.28: Setting the build events.

And finally, enter the following text into the Post-build event command line field:

```
cd "$(ProjectDir)"
cd ..\..\CrypWin\bin\Debug
if not exist ".\CrypPlugins" mkdir ".\CrypPlugins"
del /F /S /Q /s /q "Caesar *.*"
copy "$(TargetDir) Caesar *.*" ".\CrypPlugins"
```

You will need to change the highlighted fields to your particular plugin's name.

2.14 Drawing the workflow of your plugin

Each plugin should have an associated workflow file to show the algorithm in action in CrypTool 2. Such a file can be automatically created by simply saving a CrypTool 2 workspace project featuring your plugin. Below is a possible workflow for our Caesar example:

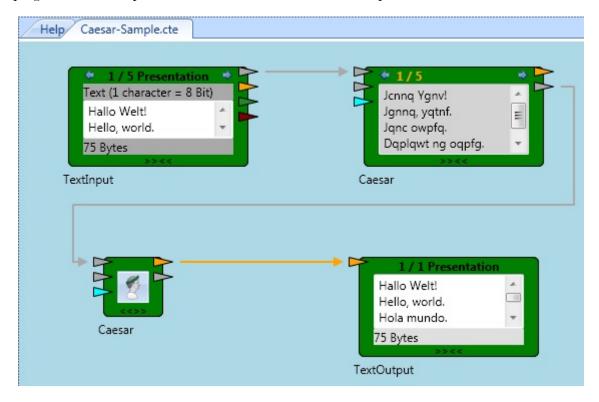

Figure 2.29: A sample workflow diagram for the Caesar algorithm.
